

# 150MHz phase-locked loop

# NE/SA568A

## DESCRIPTION

The NE568A is a monolithic phase-locked loop (PLL) which operates from 1Hz to frequencies in excess of 150MHz and features an extended supply voltage range and a lower temperature coefficient of the  $V_{CO}$  center frequency in comparison with its predecessor, the NE 568. The NE568A is function and pin-compatible with the NE568, requiring only minor changes in peripheral circuitry (see Figure 3). Temperature compensation network is different, no resistor on Pin 12, needs to be grounded and Pin 13 has a 3.9k $\Omega$  resistor to ground. Timing cap,  $C_2$ , is different and for 70MHz operation with temperature compensation network should be 16pF, not 34pF as was used in the NE568. The NE568A has the following improvements: ESD protected; extended  $V_{CC}$  range from 4.5V to 5.5V; operating temperature range -55 to 125°C (see Signetics Military 568A data sheet); less layout sensitivity; and lower  $T_C$  of VCO (center frequency). The integrated circuit consists of a limiting amplifier, a current-controlled oscillator (ICO), a phase detector, a level shift circuit, V/I and I/V converters, an output buffer, and bias circuitry with temperature and frequency compensating characteristics. The design of the NE568A is particularly well-suited for demodulation of FM signals with extremely large deviation in systems which require a highly linear output. In satellite receiver applications with a 70MHz IF, the NE568A will demodulate  $\pm 20\%$  deviations with less than 1.0% typical non-linearity. In addition to high linearity, the circuit has a loop filter which can be configured with series or shunt elements to optimize loop dynamic performance. The NE568A is available in 20-pin dual in-line and 20-pin SO (surface mounted) plastic packages.

## FEATURES

- Operation to 150MHz
- High linearity buffered output

## PIN CONFIGURATION

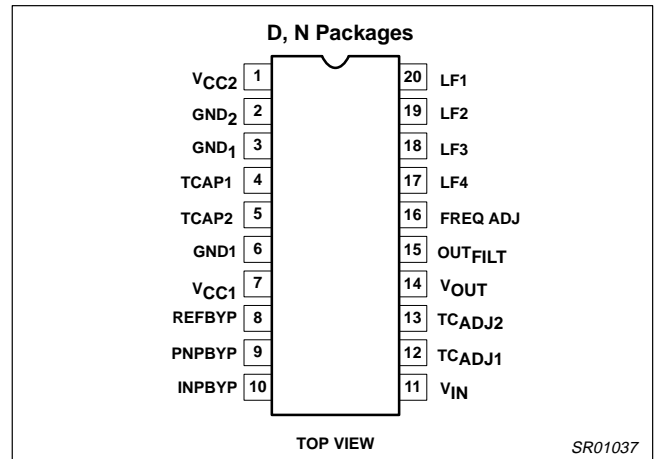

Figure 1. Pin Configuration

- Series or shunt loop filter component capability
- External loop gain control
- Temperature compensated
- ESD protected<sup>1</sup>

## APPLICATIONS

- Satellite receivers
- Fiber optic video links
- VHF FSK demodulators
- Clock Recovery

## ORDERING INFORMATION

DESCRIPTION	TEMPERATURE RANGE	ORDER CODE	DWG #
20-Pin Plastic Small Outline Large (SOL) Package	0 to +70°C	NE568AD	SOT163-1
20-Pin Plastic Dual In-Line Package (DIP)	0 to +70°C	NE568AN	SOT146-1
20-Pin Plastic Small Outline Large (SOL) Package	-40 to +85°C	SA568AD	SOT163-1
20-Pin Plastic Dual In-Line Package (DIP)	-40 to +85°C	SA568AN	SOT146-1

$P_{DMAX}$	Maximum power dissipation	400	mW
$\theta_{JA}$	Thermal resistance	80	°C/W

## ELECTRICAL CHARACTERISTICS

The electrical characteristics listed below are actual tests (unless otherwise stated) performed on each device with an automatic IC tester prior to shipment. Performance of the device in automated test set-up is not necessarily optimum. The NE568A is

layout-sensitive. Evaluation of performance for correlation to the data sheet should be done with the circuit and layout of Figures 3, 4, and 5 with the evaluation unit soldered in place. (Do not use a socket!)

## DC ELECTRICAL CHARACTERISTICS

$V_{CC} = 5V$ ;  $T_A = 25^\circ C$ ;  $f_O = 70MHz$ , Test Circuit Figure 3,  $f_{IN} = -20dBm$ ,  $R_4 = 3.9k\Omega$ , unless otherwise specified.

SYMBOL	PARAMETER	TEST CONDITIONS	LIMITS			UNITS

$f_O$	Distribution <sup>6</sup>	Centered at 70MHz, $R_2 = 1.2k\Omega$ , $C_2 = 16pF$ , $R_4 = 3.9k\Omega$ ( $C_2 + C_{STRAY} = 20pF$ )	-15	0	+15	%
$f_O$	Drift with supply	4.5V to 5.5V		2		%/V

## NOTE:

- Signal level to assure all published parameters. Device will continue to function at lower levels with varying performance.
- Limits are set symmetrical to  $f_O$ . Actual characteristics may have asymmetry beyond the specified limits.
- Not 100% tested, but guaranteed by design.
- Input impedance depends on package and layout capacitances. See Figures 6 and 5.
- Linearity is tested with incremental changes in input frequency and measurement of the DC output voltage at Pin 14 ( $V_{OUT}$ ). Non-linearity is then calculated from a straight line over the deviation range specified.
- Free-running frequency is measured as feedthrough to Pin 14 ( $V_{OUT}$ ) with no input signal applied.

## FUNCTIONAL DESCRIPTION

The NE568A is a high-performance phase-locked loop (PLL). The circuit consists of conventional PLL elements, with special circuitry for linearized demodulated output, and high-frequency performance. The process used has NPN transistors with  $f_T > 6\text{GHz}$ . The high gain and bandwidth of these transistors make careful attention to layout and bypass critical for optimum performance. The performance of the PLL cannot be evaluated independent of the layout. The use of the application layout in this data sheet and surface-mount capacitors are highly recommended as a starting point.

The input to the PLL is through a limiting amplifier with a gain of 200. The input of this amplifier is differential (Pins 10 and 11). For single-ended applications, the input must be coupled through a DC-blocking capacitor with low impedance at the frequency of interest. The single-ended input is normally applied to Pin 11 with Pin 10 AC-bypassed with a low-impedance capacitor. The input impedance is characteristically slightly above  $500\Omega$ . Impedance match is not necessary, but loading the signal source should be avoided. When the source is 50 or  $75\Omega$ , a DC-blocking capacitor is usually all that is needed.

Input amplification is low enough to assure reasonable response time in the case of large signals, but high enough for good AM rejection. After amplification, the input signal drives one port of a multiplier-cell phase detector. The other port is driven by the current-controlled oscillator (ICO). The output of the phase comparator is a voltage proportional to the phase difference of the input and ICO signals. The error signal is filtered with a low-pass filter to provide a DC-correction voltage, and this voltage is converted to a current which is applied to the ICO, shifting the frequency in the direction which causes the input and ICO to have a  $90^\circ$  phase relationship.

The oscillator is a current-controlled multivibrator. The current control affects the charge/discharge rate of the timing capacitor. It is common for this type of oscillator to be referred to as a

voltage-controlled oscillator (VCO), because the output of the phase comparator and the loop filter is a voltage. To control the frequency of an integrated ICO multivibrator, the control signal must be conditioned by a voltage-to-current converter. In the NE568A, special circuitry predistorts the control signal to make the change in frequency a linear function over a large control-current range.

The free-running frequency of the oscillator depends on the value of the timing capacitor connected between Pins 4 and 5. The value of the timing capacitor depends on internal resistive components and current sources. When  $R_2 = 1.2\text{k}\Omega$  and  $R_4 = 0\Omega$ , a very close approximation of the correct capacitor value is:

$$C^* = \frac{0.0014}{f_O} \text{ F}$$

where

$$C^* = C_2 + C_{\text{STRAY}}$$

The temperature-compensation resistor,  $R_4$ , affects the actual value of capacitance. This equation is normalized to 70MHz. See 10 for correction factors.

The loop filter determines the dynamic characteristics of the loop. In most PLLs, the phase detector outputs are internally connected to the ICO inputs. The NE568A was designed with filter output to input connections from Pins 20 ( $\phi$  DET) to 17 (ICO), and Pins 19 ( $\phi$  DET) to 18 (ICO) external. This allows the use of both series and shunt loop-filter elements. The loop constraints are:

$$K_O = 0.12\text{V/Radian (Phase Detector Constant)}$$

$$K_O = 4.2 \cdot 10^9 \frac{\text{Radians}}{\text{V-sec}} \text{ (ICO Constant) at 70MHz}$$

The loop filter determines the general characteristics of the loop. Capacitors  $C_9$ ,  $C_{10}$ , and resistor  $R_1$ , control the transient output of the phase detector. Capacitor  $C_9$  suppresses 70MHz feedthrough by interaction with  $100\Omega$  load resistors internal to the phase detector.

## 150MHz phase-locked loop

## NE/SA568A

$$C_9 = \frac{1}{2\pi (50) (f_0)} F$$

At 70MHz, the calculated value is 45pF. Empirical results with the test and application board were improved when a 47pF capacitor was used.

The natural frequency for the loop filter is set by  $C_{10}$  and  $R_1$ . If the center frequency of the loop is 70MHz and the full demodulated bandwidth is desired, i.e.,  $f_{BW} = f_0/7 = 10\text{MHz}$ , and a value for  $R_1$  is chosen, the value of  $C_{10}$  can be calculated.

$$C_{10} = \frac{1}{2\pi R_1 f_{BW}} F$$

Also,

$$C_{11} = \frac{1}{2\pi 350\Omega f_{BW(\text{Hz})}}$$

This capacitance determines the signal bandwidth of the output buffer amplifier. (For further information see Philips application note AN1881 "The NE568A Phase Locked Loop as a Wideband Video Demodulator".

## NOTES:

- 18pF with Pin 12 ground and Pin 13 no connect (open).
- $C_2 + C_{\text{STRAY}} = 16\text{pF}$  for temperature-compensated configuration with  $R_4 = 3.9\text{k}\Omega$ .
- For 50Ω setup.  $R_1 = 62\Omega$ ,  $R_3 = 75\Omega$  for 75Ω application.
- For test configuration  $R_4 = 0\Omega$  (GND) and  $C_2 = 18\text{pF}$ .
- 0Ω chip resistors (jumpers) may be substituted with minor degradation of performance.
