Hello Maohamed,

The 63 Hz is for maximum line frequency based on the US line frequency of $60 \mathrm{~Hz}+/-5 \%$ and is needed to calculate the input bulk capacitor (Cbulk), equation 18 in the data sheet.

The active clamp fly back is similar to a quasi-resonate fly back which is critical conduction. However, the active clamp allows bidirectional current in the primary of the transformer. So the input current of the transformer goes in the reverse negative direction. Please refer to figure 46 in the data sheet that give an example of what the transformer primary current looks like.

Figure 23 shows how the switching frequency changes with output current (lo). I have added $\mathrm{I}_{\mathrm{FB}}$ to show how the operation mode moves with FB current. When $\mathrm{I}_{\mathrm{FB}}=0 \mathrm{uA}$ fsw is at $\mathrm{fsw}(\mathrm{min})$. When $\mathrm{I}_{\mathrm{FB}}=58 \mathrm{uA}$ the design is operating at fsw(max)

Each mode of operation is described in table 1.

Table 1. Functional Modes

|  | MODE | OPERATION | PWMH | ZVS |
| :---: | :--- | :--- | :---: | :---: |
| AAM | Adaptive <br> Amplitude <br> Modulation | ACF operation with PWML and PWMH in complementary <br> switching | Enabled | Yes |
| ABM | Adaptive Burst <br> Mode | Variable $f_{\text {BUR }}>20 \mathrm{kHz}$, ACF operation in complementary <br> switching | Enabled | Yes |
| LPM | Low Power Mode | Fix $f_{\text {BUR }} \approx 25 \mathrm{kHz}$, valley-switching | Disabled | No |
| SBP | StandBy Power | Variable $f_{\text {BUR }}<25 \mathrm{kHz}$, valley-switching | Disabled | No |

Please note that your switching frequency will vary based on the primary magnetizing inductance ( $L_{M}$ ) efficiency and burst level that you have chosen for your design. You select $L_{M}$ based on maximum output power an estimated efficiency and what level you set your peak current to (Vcst(bur). This is covered in section 7.3 of the data sheet.

### 8.2.2.2.2 Primary Magnetizing Inductance ( $\mathrm{L}_{\mathrm{M}}$ )

After $N_{P S}$ is chosen, $L_{M}$ can be estimated based on minimum switching frequency ( $f_{\text {SW(MIN) }}$ ) at $V_{B U L K(M I N)}$, maximum duty cycle ( $\mathrm{D}_{\text {MAX }}$ ), and output power at nominal full load current ( $\mathrm{P}_{\mathrm{O}(\mathrm{FL})}$ ). $\mathrm{K}_{\text {RES }}$ represents the duty cycle loss to wait for the switch-node voltage transition from the reflected output voltage to zero. $5 \%$ to $6 \%$ of $\mathrm{K}_{\text {RES }}$ is used as a initial estimated value. The selection of minimum switching frequency ( $\mathrm{f}_{\mathrm{SW}(\mathrm{MIN})}$ ) has to consider the impact on full-load efficiency and EMI filter design.

$$
\begin{align*}
& D_{M A X}=\frac{N_{P S}\left(V_{O}+V_{F}\right)}{V_{B U L K(M I N)}+N_{P S}\left(V_{O}+V_{F}\right)}  \tag{22}\\
& L_{M}=\frac{D_{M A X}{ }^{2} V_{B U L K(M I N)} \eta}{2 P_{O(F L)}} \times \frac{\left(1-K_{R E S}\right)}{f_{S W(M I V)}} \tag{23}
\end{align*}
$$

With Vcst(max) and Vcst(min) typicals of 800 mV and 150 mV . You should be able to rough estimate what switching frequency the converter should be operating at.

| CS INPUT |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {CST }}$ (MAX) | Maximum CS threshold voltage | $\mathrm{V}_{\text {CS }}$ increasing | 765 | 800 | 825 | mV |
| $\mathrm{V}_{\text {CST(MIN) }}$ | Minimum CS threshold voltage | $\mathrm{V}_{\mathrm{CS}}$ decreasing, $\mathrm{I}_{\mathrm{FB}}=-85 \mu \mathrm{~A}$ | 123 | 150 | 170 | mV |

Ton $=(\text { Lm/Vbulk })^{*}$ Vcst/Rcs
$\operatorname{Pmax} \approx\left((\operatorname{Rcs} /(\mathrm{Vcst}(\mathrm{opp})) * 2) * \operatorname{ton}^{*} \mathrm{fsw}(\mathrm{min}) *\right.$ Vbulk, $\mathrm{I}_{\mathrm{FB}}=0 \mathrm{uA}$
Vcst(bur) is what you program section 7.3 of the data sheet.
