

DAC39J82 Dual-Channel, 16-Bit, 2.8 GSPS, Digital-to-Analog Converter with 12.5 Gbps JESD204B Interface

1 Features

- Resolution: 16-Bit
- Maximum Sample Rate: 2.8GSPS
- Maximum Input Data Rate: 1.4GSPS
- JESD204B Interface
 - 8 JESD204B Serial Input Lanes
 - 12.5 Gbps Maximum Bit Rate per Lane
 - Subclass 1 Multi-DAC synchronization
- On-Chip Very Low Jitter PLL
- Selectable 1x -16x Interpolation
- Independent Complex Mixers with 48-bit NCO/ or $\pm n \times F_s/8$
- Wideband Digital Quadrature Modulator Correction
- $\sin x/x$ Correction Filters
- Fractional Sample Group Delay Correction
- Flexible Routing to Four Analog Outputs via Output Multiplexer
- 3/4-Wire Serial Control Bus (SPI)
- Integrated Temperature Sensor
- JTAG Boundary Scan
- Pin-compatible with Quad-channel DAC39J84
- Power Dissipation: 1.1W at 2.8GSPS
- Package: 10x10mm, 144-Ball Flip-Chip BGA

2 Applications

- Cellular Base Stations
- Diversity Transmit
- Wideband Communications
- Direct Digital Synthesis (DDS) Instruments
- Millimeter/Microwave Backhaul
- Automated Test Equipment
- Cable Infrastructure
- Radar

3 Description

The DAC39J82 is a very low power, 16-bit, dual-channel, 2.8 GSPS digital to analog converter (DAC) with JESD204B interface. The maximum input data rate is 1.4 GSPS.

Digital data is input to the device through 1, 2, 4 or 8 configurable serial JESD204B lanes running up to 12.5 Gbps with on-chip termination and programmable equalization. The interface allows JESD204B Subclass 1 SYSREF based deterministic latency and full synchronization of multiple devices.

The device includes features that simplify the design of complex transmit architectures. Fully bypassable 2x to 16x digital interpolation filters with over 90 dB of stop-band attenuation simplify the data interface and reconstruction filters. An on-chip 48-bit Numerically Controlled Oscillator (NCO) and independent complex mixers allow flexible and accurate carrier placement.

A high-performance low jitter PLL simplifies clocking of the device without significant impact on the dynamic range. The digital Quadrature Modulator Correction (QMC) and Group Delay Correction (QDC) enable complete IQ compensation for gain, offset, phase, and group delay between channels in direct up-conversion applications. A programmable Power Amplifier (PA) protection mechanism is available to provide PA protection in cases when the abnormal power behavior of the input data is detected.

DAC39J82 provides four analog outputs, and the data from the internal two digital paths can be routed to any two out of these four DAC outputs via the output multiplexer.

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
DAC39J82	FCBGA (144)	10.00 mm x 10.00 mm

(1) For all available packages, see the orderable addendum at the end of the datasheet.

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NUMBER		
ALARM	L8	O	CMOS output for ALARM condition. The ALARM output functionality is defined through the <i>config7</i> register. Default polarity is active high, but can be changed to active high via <i>config0 alarm_out_pol</i> control bit. If not used it can be left open.
AMUX0	H3	I/O	Analog test pin for SerDes, Lane 0 to Lane 3. It can be left open if not used.
AMUX1	E3	I/O	Analog test pin for SerDes, Lane 4 to Lane 7. It can be left open if not used.
ATEST	K9	I/O	Analog test pin for DAC, references and PLL. It can be left open if not used.
DACCLKP	A10	I	Positive LVPECL clock input for DAC core with $V_{cm} = 0.5V$. It can be PLL reference clock or external DAC sampling rate clock. If not used, DACCLK is self-biased with 100mV differential at $V_{cm} = 0.5V$.
DACCLKN	A9	I	Complementary LVPECL clock input for DAC core. (see the DACCLKP description)
EXTIO	F10	I/O	Used as external reference input when internal reference is disabled through <i>config27 extref_ena = '1'</i> . Used as internal reference output when <i>config27 extref_ena = '0'</i> (default). Requires a 0.1 μF decoupling capacitor to analog GND when used as reference output. It can be left open if not used.
GND	A12, F12, G12, M12, A11, B11, C11, D11, E11, F11, G11, H11, J11, K11, L11, M11, C8, D8, E8, F8, G8, H8, J8, E7, F7, G7, H7, E6, F6, G6, H6, A5, B5, E5, F5, G5, H5, A4, B4, M4, B3, C3, L3, B2, C2, D2, E2, H2, J2, K2, L2	I	These pins are ground for all supplies.
IFORCE	C5	I/O	Analog test pin for on chip parametric. It can be left open if not used.
IOUTAP	B12	O	A-Channel DAC current output. Must be tied to GND if not used.
IOUTAN	C12	O	A-Channel DAC complementary current output. Must be tied to GND if not used.
IOUTBP	E12	O	B-Channel DAC current output. Must be tied to GND if not used.
IOUTBN	D12	O	B-Channel DAC complementary current output. Must be tied to GND if not used.
IOUTCP	H12	O	C-Channel DAC current output. Must be tied to GND if not used.
IOUTCN	J12	O	C-Channel DAC complementary current output. Must be tied to GND if not used.
IOUTDP	L12	O	D-Channel DAC current output. Must be tied to GND if not used.
IOUTDN	K12	O	D-Channel DAC complementary current output. Must tied to GND if not used.
LPF	C9	I/O	External PLL loop filter connection. It can be left open if not used.
RBIAS	G10	O	Full-scale output current bias. Change the full-scale output current through <i>coarse_dac(3:0)</i> . Expected to be 1.92k Ω to GND.
RESETB	K8	I	Active low input for chip RESET, which resets all the programming registers to their default state. Internal pull-up. It can be left open if not used.
RX0P	G1	I	CML SerDes interface lane 0 input, positive, expected to be AC coupled. It can be left open if not used.
RX0N	H1	I	CML SerDes interface lane 0 input, negative, expected to be AC coupled. It can be left open if not used.
RX1P	K1	I	CML SerDes interface lane 1 input, positive, expected to be AC coupled. It can be left open if not used.
RX1N	J1	I	CML SerDes interface lane 1 input, negative, expected to be AC coupled. It can be left open if not used.
RX2P	L1	I	CML SerDes interface lane 2 input, positive, expected to be AC coupled. It can be left open if not used.
RX2N	M1	I	CML SerDes interface lane 2 input, negative, expected to be AC coupled. It can be left open if not used.
RX3P	M3	I	CML SerDes interface lane 3 input, positive, expected to be AC coupled. It can be left open if not used.

Pin Functions (continued)

PIN		I/O	DESCRIPTION
NAME	NUMBER		
RX3N	M2	I	CML SerDes interface lane 3 input, negative, expected to be AC coupled. It can be left open if not used.
RX4P	F1	I	CML SerDes interface lane 4 input, positive, expected to be AC coupled. It can be left open if not used.
RX4N	E1	I	CML SerDes interface lane 4 input, negative, expected to be AC coupled. It can be left open if not used.
RX5P	C1	I	CML SerDes interface lane 5 input, positive, expected to be AC coupled. It can be left open if not used.
RX5N	D1	I	CML SerDes interface lane 5 input, negative, expected to be AC coupled. It can be left open if not used.
RX6P	B1	I	CML SerDes interface lane 6 input, positive, expected to be AC coupled. It can be left open if not used.
RX6N	A1	I	CML SerDes interface lane 6 input, negative, expected to be AC coupled. It can be left open if not used.
RX7P	A3	I	CML SerDes interface lane 7 input, positive, expected to be AC coupled. It can be left open if not used.
RX7N	A2	I	CML SerDes interface lane 7 input, negative, expected to be AC coupled. It can be left open if not used.
SYSREFP	A7	I	LVPECL SYSREF positive input with $V_{cm} = 0.5V$. This positive/negative pair is captured with the rising edge of DACCLKP/N. It is used for JESD204B Subclass 1 deterministic latency and multiple DAC synchronization, which can be periodic or pulsed. If not used, it is self-biased with 100mV differential at $V_{cm} = 0.5V$.
SYSREFN	A6	I	LVPECL SYSREF negative input with $V_{cm} = 0.5V$. (See the SYSREFP description)
SCLK	L9	I	Serial interface clock. Internal pull-down. It can be left open if not used.
SDENB	M9	I	Active low serial data enable, always an input to the DAC39J82. Internal pull-up. It can be left open if not used.
SDIO	L10	I/O	Serial interface data. Bi-directional in 3-pin mode (default) and 4-pin mode. Internal pull-down. It can be left open if not used.
SDO	M10	O	Uni-directional serial interface data in 4-pin mode. The SDO pin is tri-stated in 3-pin interface mode (default). It can be left open if not used.
SLEEP	M8	I	Active high asynchronous hardware power-down input. Internal pull-down. It can be left open if not used.
SYNCBP	B7	O	Synchronization request to transmitter, LVDS positive output. It can be left open if not used.
SYNCBN	B6	O	Synchronization request to transmitter, LVDS negative output. It can be left open if not used.
SYNC_N_AB	L6	O	Synchronization request to transmitter, CMOS output. Defaults to link 0, but can be programmable for any link. It can be left open if not used.
SYNC_N_CD	L7	O	Synchronization request to transmitter, CMOS output. Defaults to link 1, but can be programmable for any link. It can be left open if not used.
TCLK	K4	I	JTAG test clock. It can be left open if not used.
TDI	L5	I	JTAG test data in. It can be left open if not used.
TDO	M5	O	JTAG test data out. It can be left open if not used.
TMS	L4	I	JTAG test mode select. It can be left open if not used.
TRSTB	J3	I	JTAG test reset. Must be tied to GND to hold the JTAG state machine status reset if the JTAG port is not used.
TXENABLE	K5	I	To enable analog output data transmission, set <i>sif_txenable</i> in register <i>config3</i> to "1" or pull CMOS TXENABLE pin to high. Transmit enable active high input. Internal pull-down. To disable analog output, set <i>sif_txenable</i> to "0" and pull CMOS TXENABLE pin to low. The DAC output is forced to midscale. It can be left open if not used.
TESTMODE	K3	O	This pin is used for factory testing. Internal pull-down. It can be left open if not used.
VDDADAC33	D10, E10, H10, J10,	I	Analog supply voltage. (3.3V)
VDDAPLL18	B10, B9	I	PLL analog supply voltage. (1.8V)
VDDAREF18	C10, K10	I	Analog reference supply voltage (1.8V)

Pin Functions (continued)

PIN		I/O	DESCRIPTION
NAME	NUMBER		
VDDCLK09	A8, B8	I	Internal clock buffer supply voltage (0.9V). It is recommended to isolate this supply from VDDDIG09.
VDDDAC09	D9, E9, F9, G9, H9, J9	I	DAC core supply voltage. (0.9V). It is recommended to isolate this supply from VDDDIG09.
VDDDIG09	J7, J6, D5, J5, D4, E4, F4, G4, H4, J4, D3	I	Digital supply voltage. (0.9V). It is recommended to isolate this supply from VDDCLK09 and VDDDAC09.
VDDIO18	K7, K6	I	Supply voltage for all digital I/O and CMOS I/O. (1.8V)
VDDR18	F2, G2	I	Supply voltage for SerDes (1.8V)
VDDS18	C7, C6	I	Supply voltage for LVDS SYNCBP/N (1.8V)
VDDT09	F3, G3	I	Supply voltage for SerDes termination (0.9V)
VQPS18	D7, D6	I	Fuse supply voltage. This supply pin is also used for factory fuse programming. Connect to 1.8V.
VSENSE	C4	I/O	Analog test pin for on chip parametric. It can be left open if not used.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

	AMUX1, AMUX0	–0.5 V	VDDT09 + 0.5 V	V
Peak input current (any input)			20	mA
Peak total input current (all inputs)			–30	mA
Absolute maximum junction temperature T _J			150	°C
Operating free-air temperature range, T _A : DAC39J82		–40	85	°C

- (1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only and functional operation of these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

- (2) Measured with respect to GND.

6.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	1000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	250	

- (1) Level listed above is the passing level per ANSI, ESDA, and JEDEC JS-001. JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) Level listed above is the passing level per EIA-JEDEC JESD22-C101. JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

		MIN	NOM	MAX	UNIT
T _J	Recommended operating junction temperature			105	°C
	Maximum rated operating junction temperature ⁽¹⁾	125			°C
T _A	Recommended free-air temperature	-40	25	85	°C

- (1) Prolonged use at this junction temperature may increase the device failure-in-time (FIT) rate.

6.4 Thermal Information

THERMAL CONDUCTIVITY ⁽¹⁾		DAC39J82	UNIT
		AAV (144 PINS)	
R _{θJA}	Theta junction-to-ambient (still air)	31.4	°C/W
R _{θJB}	Theta junction-to-board	12.6	
R _{θJC}	Theta junction-to-case, top	1.8	
Ψ _{JT}	Psi junction-to-top of package	0.2	
Ψ _{JB}	Psi junction-to-bottom of package	12	

- (1) Air flow or heat sinking reduces θ_{JA} and may be required for sustained operation at 85° and maximum operating conditions.

6.5 DC Electrical Characteristics

Typical values at T_A = 25°C, full temperature range is T_{MIN} = -40°C to T_{MAX} = 85°C, nominal supplies, unless otherwise noted.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT

7 Detailed Description

7.1 Overview

The DAC39J82 is a very low power, 16-bit, 2.8 GSPS digital-to-analog converter (DAC) with JESD204B interface up to 12.5 Gbps. The maximum input data rate is 1.4 GSPS. The DAC39J82 is also pin-compatible with the 16-bit, dual-channel, 1.6/2.5 GSPS DAC37J82/DAC38J82.

Digital data is input to the device through 1, 2, 4 or 8 configurable serial JESD204B lanes running up to 12.5 Gbps with on-chip termination and programmable equalization. The interface allows JESD204B Subclass 1 SYSREF based deterministic latency and full synchronization of multiple devices.

The device includes features that simplify the design of complex transmit architectures. Fully bypassable 2x to 16x digital interpolation filters with over 90 dB of stop-band attenuation simplify the data interface and reconstruction filters. An on-chip 48-bit Numerically Controlled Oscillator (NCO) and independent complex mixers allow flexible and accurate carrier placement. A high-performance low jitter PLL simplifies clocking of the device without significant impact on the dynamic range. The digital Quadrature Modulator Correction (QMC) and Group Delay Correction (GDC) enable complete wideband IQ compensation for gain, offset, phase, and group delay between channels in direct up-conversion applications. A programmable Power Amplifier (PA) protection mechanism is available to provide PA protection in cases when the abnormal power behavior of the input data is detected.

DAC39J82 provides four analog outputs, and the data from the internal two digital paths can be routed to any two out of these four DAC outputs via the output multiplexer.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Serdes Input

The RX[7:0]P/N differential inputs are each internally terminated to a common point via 50 Ω , as shown in Figure 55.

Figure 55. Serial Lane Input Termination

Common mode termination is via a 50-pF capacitor to GND. The common mode voltage and termination of the differential signal can be controlled in a number of ways to suit a variety of applications via *rw_cfgrx0* [10:8] (**TERM**), as described in Table 1.

(Note: AC coupling is recommended for JESD204B compliance.)

Table 1. Receiver Termination Selection

TERM	EFFECT
000	Reserved
001	Common point set to 0.7 V. This configuration is for AC coupled systems. The transmitter has no effect on the receiver common mode, which is set to optimize the input sensitivity of the receiver.
01x	Reserved
100	Common point set to GND. This configuration is for applications that require a 0-V common mode.
101	Common point set to 0.25 V. This configuration is for applications that require a low common mode.
110	Reserved
111	Common point floating. This configuration is for DC coupled systems in which the common mode voltage is set by the attached transmit link partner to 0 and 0.6 V. Note: this mode is not compatible with JESD204B.

Data input is sampled by the differential sensing amplifier using clocks derived from the clock recovery algorithm. The polarity of RXP and RXN can be inverted by setting the **INVPAIR** [7:0] bit of the corresponding lane to “1”. This can potentially simplify PCB layout and improve signal integrity by avoiding the need to swap over the differential signal traces.

Due to processing effects, the devices in the RXP and RXN differential sense amplifiers will not be perfectly matched and there will be some offset in switching threshold. DAC39J82 contains circuitry to detect and correct for this offset. This feature can be enabled by setting the *rw_cfgrx0* [23] (**ENOC**) bit to “1”. It is anticipated the most users will enable this feature. During the compensation process, *rw_cfgrx0* [25:24] (**LOOPBACK**) bit must be set to “00”.

7.3.2 Serdes Rate

The DAC39J82 has 8 configurable JESD204B serial lanes. The highest speed of each SerDes lane is 12.5 Gbps. Because the primary operating frequency of the SerDes is determined by its reference clock and PLL multiplication factor, there is a limit on the lowest SerDes rate supported, refer to Table 2 for details. To support lower speed application, each receiver should be configured to operate at half, quarter or eighth of the full rate via *rw_cfgrx0* [6:5] (**RATE**).

Table 2. Lane Rate Selection

RATE	EFFECT
00	<i>Full rate.</i> Four data samples taken per SerDes PLL output clock cycle.
01	<i>Half rate.</i> Two data samples taken per SerDes PLL output clock cycle..
10	<i>Quarter rate.</i> One data samples taken per SerDes PLL output clock cycle.
11	<i>Eighth rate.</i> One data samples taken every two SerDes PLL output clock cycles.

7.3.3 Serdes PLL

The DAC39J82 has two integrated PLLs, one PLL is to provide the clocking of DAC, which will be discussed in a DAC PLL section; the other PLL is to provide the clocking for the high speed SerDes. The reference frequency of the SerDes PLL can be in the range of 100-800MHz nominal, and 300-800 MHz optimal.

The reference frequency is derived from DACCLK divided down based on the *serdes_refclk_div* programming, as shown in Figure 56.

Figure 56. Reference Clock of SerDes PLL

During normal operation, the clock generated by PLL will be 4-25 times the reference frequency, according to the multiply factor selected via *rw_cfgpll* [8:1] (**MPY**). In order to select the appropriate multiply factor and refclkp/n frequency, it is first necessary to determine the required PLL output clock frequency. The relationship between the PLL output clock frequency and the lane rate is shown in Table 3. Having computed the PLL output frequency, the reference frequency can be obtained by dividing this by the multiply factor specified via **MPY**.

NOTE

High multiplication factor settings will be especially sensitive to reference clock jitter and should not be employed without prior consultation with TI.

Table 3. Relationship Between Lane Rate and SerDes PLL Output Frequency

RATE	LINE RATE	PLL OUTPUT FREQUENCY
Full	x Gbps	0.25x GHz
Half	x Gbps	0.5x GHz

Table 3. Relationship Between Lane Rate and SerDes PLL Output Frequency (continued)

RATE	LINE RATE	PLL OUTPUT FREQUENCY
Quarter	x Gbps	1x GHz
Eighth	x Gbps	2x GHz

Table 4. SerDes PLL Modes Selection

MPY	EFFECT
00010000	4x
00010100	5x
00011000	6x
00100000	8x
00100001	8.25x
00101000	10x
00110000	12x
00110010	12.5x
00111100	15x
01000000	16x
01000010	16.5x
01010000	20x
01011000	22x
01100100	25x
Other codes	reserved

The wide range of multiply factors combined with the different rate modes means it will often be possible to achieve a given line rate from multiple different reference frequencies. The configuration which utilizes the highest reference frequency achievable is always preferable.

The SerDes PLL VCO must be in the nominal range of 1.5625 - 3.125 GHz. It is necessary to adjust the loop filter depending on the operating frequency of the VCO. To indicate the selection the user must set the ***rw_cfgpll*** [9] (**VRANGE**) bit. If the PLL output frequency is below 2.17 GHz, **VRANGE** should be set high.

Performance of the integrated PLL can be optimized according to the jitter characteristics of the reference clock by setting the appropriate loop bandwidth via ***rw_cfgpll*** [12:11] (**LB**) bits. The loop bandwidth is obtained by dividing the reference frequency by BWSCALE, where the BWSCALE is a function of both LB and PLL output frequency as shown in [Table 5](#).

Table 5. SerDes PLL Loop Bandwidth Selection

LB	EFFECT	BWSCALE vs PLL OUTPUT FREQUENCY		
		3.125 GHz	2.17 GHz	1.5625 GHz
00	Medium loop bandwidth	13	14	16
01	Ultra high loop bandwidth	7	8	8
10	Low loop bandwidth	21	23	30
11	High loop bandwidth	10	11	14

An approximate loop bandwidth of 8–30 MHz is suitable and recommended for most systems where the reference clock is via low jitter clock input buffer. For systems where the reference clock is via a low jitter input cell, but of low quality, an approximate loop bandwidth of less than 8 MHz may offer better performance. For systems where the reference clock is cleaned via an ultra low jitter LC-based cleaner PLL, a high loop bandwidth up to 60MHz is more appropriate. Note that the use of ultra high loop bandwidth setting is not recommended for PLL multiply factor of less than 8.

A free running clock output is available when ***rw_cfgpll*** [15:14] (**ENDIVCLK**) is set high. It runs at a fixed divided-by-5 of the PLL output frequency and has a duty cycle of 50%. A divided-by-16 of this free running clock can be configured to come out the alarm pin during digital test, see ***dtest*** [11:8] for the specific configuration needed.

7.3.4 Serdes Equalizer

All channels of the DAC39J82 incorporate an adaptive equalizer, which can compensate for channel insertion loss by attenuating the low frequency components with respect to the high frequency components of the signal, thereby reducing inter-symbol interference. Figure 57 shows the response of the equalizer, which can be expressed in terms of the amount of low frequency gain and the frequency up to which this gain is applied (i.e., the frequency of the 'zero'). Above the zero frequency, the gain increases at 6dB/octave until it reaches the high frequency gain.

Figure 57. Equalizer Frequency Response

The equalizer can be configured via ***rw_cfgrx0***[21:19] (**EQ**) and ***rx_cfgrx0***[22] (**EQHLD**). Table 6 and Table 7 summarize the options. When enabled, the receiver equalization logic analyzes data patterns and transition times to determine whether the low frequency gain should be increased or decreased. The decision logic is implemented as a voting algorithm with a relatively long analysis interval. The slow time constant that results reduces the probability of incorrect decisions but allows the equalizer to compensate for the relatively stable response of the channel. The lock time for the adaptive equalizer is data dependent, and so it is not possible to specify a generally applicable absolute limit. However, assuming random data, the maximum lock time will be 6×10^6 divided by the CDR activity level. For CDR (***rw_cfgrx0***[18:16]) = 110, this is 1.5×10^6 UI.

When **EQ[2]** = 0, finer control of gain boost is available using the EQBOOSTi IEEE1500 tuning chain field, as shown in Table 8.

Table 6. Receiver Equalization Configuration

EQ		EFFECT
[1:0]	0	No equalization. The equalizer provides a flat response at the maximum gain. This setting may be appropriate if jitter at the receiver occurs predominantly as a result of crosstalk rather than frequency dependent loss.
	1	Fully adaptive equalization. The zero position is determined by the selected operating rate, and the low frequency gain of the equalizer is determined algorithmically by analyzing the data patterns and transition positions in the received data. This setting should be used for most applications.
	10	Precursor equalization analysis. The data patterns and transition positions in the received data are analyzed to determine whether the transmit link partner is applying more or less precursor equalization than necessary.
	11	Postcursor equalization analysis. The data patterns and transition positions in the received data are analyzed to determine whether the transmit link partner is applying more or less postcursor equalization than necessary.
[2]	0	Default
	1	Boost. Equalizer gain boosted by 6dB, with a 20% reduction in bandwidth, and an increase of 5mW power consumption. May improve performance over long links.

Table 7. Receiver Equalizer Hold

EQHOLD	EFFECT
0	<i>Equalizer adaption enabled.</i> The equalizer adaption and analysis algorithm is enabled. This should be the default state.
1	<i>Equalizer adaption held.</i> The equalizer is held in it's current state. Additionally, the adaption and analysis algorithm is reset. See section 7.2.5.1 for further details..

Table 8. Receiver Equalizer Gain Boost

EQBoost VALUE	GAIN BOOST (dB)	BANDWIDTH CHANGE (%)	POWER INCREASE (mW)
0	0	0	0
1	2	–30	0
10	4	10	5
11	6	–20	5

When EQ is set to 010 or 011, the equalizer is reconfigured to provide analytical data about the amount of pre and post cursor equalization respectively present in the received signal. This can in turn be used to adjust the equalization settings of the transmitting link partner, where a suitable mechanism for communicating this data back to the transmitter exists. Status information is provided via **adtest**[11:8] (EQOVER, EQUNDER), by using the following method:

1. Enable the equalizer by setting EQHLD low and EQ to 001. Allow sufficient time for the equalizer to adapt;
2. Set EQHLD to 1 to lock the equalizer and reset the adaption algorithm. This also causes both EQOVER and EQUNDER to become low;
3. Wait at least 48UI, and proportionately longer if the CDR activity is less than 100%, to ensure the 1 on EQHLD is sampled and acted upon;
4. Set EQ to 010 or 011, and EQHLD to 0. The equalization characteristics of the received signal are analyzed (the equalizer response will continue to be locked);
5. Wait at least $150 \times 10^3 \text{UI}$ to allow time for the analysis to occur, proportionately longer if the CDR activity is less than 100%;
6. Examine EQOVER and EQUNDER for results of analysis.
 - If EQOVER is high, it indicates the signal is over equalized;
 - If EQUNDER is high, it indicates the signal is under equalized;
7. Set EQHLD to 1;
8. Repeat items 3–7 if required;
9. Set EQ to 001, and EQHLD to 0 to exit analysis mode and return to normal adaptive equalization.

Note that when changing EQ from one non-zero value to another, EQHLD must already be 1. If this is not the case, there is a chance the equalizer could be reset by a transitory input state (i.e., if EQ is momentarily 000). EQHLD can be set to 0 at the same time as EQ is changed.

As the equalizer adaption algorithm is designed to equalize the post cursor, EQOVER or EQUNDER will only be set during post cursor analysis if the amount of post cursor equalization required is more or less than the adaptive equalizer can provide.

7.3.5 JESD204B Descrambler

The descrambler is a 16-bit parallel self-synchronous descrambler based on the polynomial $1 + x^{14} + x^{15}$. From the JESD204B specification, the scrambling/descrambling process only occurs on the user data, not on the code group synchronization or the ILA sequence. The descrambler output can be selected to sent out during JESD test, see **jesd_testbus_sel** for the specific configuration needed.

7.3.6 JESD204B Frame Assembly

The JESD204B defines the following parameters:

- L is the number of lanes per link
- M is the number of converters per device
- F is the number of octets per frame clock period

- S is the number of samples per frame
- HD is the High-Density bit which controls whether a sample may be divided over more lanes.

Table 9 list the available JESD204B formats for the DAC39J82. Table 10 and Table 11 list the speed limits of DAC39J82. The ranges are limited by the Serdes PLL VCO frequency range, the Serdes PLL reference clock range, the maximum Serdes line rate, and the maximum DAC sample frequency.

L = # of lanes

M = # of DACs

F = # of Octets per lane per frame cycle

S = # of Samples per DAC per frame cycle

HD = High density mode

 f_{SERDES} = Serdes line rate

 f_{DATA} = Input data rate per DAC

 f_{DAC} = Output sample rate

BW = Complex bandwidth (= $f_{\text{DATA}} \times 0.8$ with interpolation, = f_{DATA} without interpolation)

7.3.7 Serial Peripheral Interface (SPI)

The serial port of the DAC39J82 is a flexible serial interface which communicates with industry standard microprocessors and microcontrollers. The interface provides read/write access to all registers used to define the operating modes of the DAC39J82. It is compatible with most synchronous transfer formats and can be configured as a 3 or 4 pin interface by *sif4_ena* in register *config2*. In both configurations, SCLK is the serial interface input clock and SDENB is serial interface enable. For 3 pin configuration, SDIO is a bidirectional pin for both data in and data out. For 4 pin configuration, SDIO is bidirectional and SDO is data out only. Data is input into the device with the rising edge of SCLK. Data is output from the device on the falling edge of SCLK.

Each read/write operation is framed by signal SDENB (Serial Data Enable Bar) asserted low. The first frame byte is the instruction cycle which identifies the following data transfer cycle as read or write as well as the 7-bit address to be accessed. [Table 11](#) indicates the function of each bit in the instruction cycle and is followed by a detailed description of each bit. The data transfer cycle consists of two bytes.

Table 11. Instruction Byte of the Serial Interface

BIT	7 (MSB)	6	5	4	3	2	1	0 (LSB)
Description	R/W	A6	A5	A4	A3	A2	A1	A0

R/W Identifies the following data transfer cycle as a read or write operation. A high indicates a read operation from the DAC39J82 and a low indicates a write operation to the DAC39J82.

[A6 : A0] Identifies the address of the register to be accessed during the read or write operation.

[Figure 58](#) shows the serial interface timing diagram for a DAC39J82 write operation. SCLK is the serial interface clock input to the DAC39J82. Serial data enable SDENB is an active low input to the DAC39J82. SDIO is serial data in. Input data to the DAC39J82 is clocked on the rising edges of SCLK.

Figure 58. Serial Interface Write Timing Diagram

[Figure 59](#) shows the serial interface timing diagram for a DAC39J82 read operation. SCLK is the serial interface clock input to the DAC39J82. Serial data enable SDENB is an active low input to the DAC39J82. SDIO is serial data in during the instruction cycle. In 3 pin configuration, SDIO is data out from the DAC39J82 during the data transfer cycle, while SDO is in a high-impedance state. In 4 pin configuration, both SDIO and SDO are data out from the DAC39J82 during the data transfer cycle. At the end of the data transfer, SDIO and SDO will output low on the final falling edge of SCLK until the rising edge of SDENB when they will 3-state.

Figure 59. Serial Interface Read Timing Diagram

In the SIF interface there are four types of registers:

- **NORMAL:** The NORMAL register type allows data to be written and read from. All 16-bits of the data are registered at the same time. There is no synchronizing with an internal clock thus all register writes are asynchronous with respect to internal clocks. There are three subtypes of NORMAL:
 - **AUTOSYNC:** A NORMAL register that causes a sync to be generated after the write is finished. These are used when it is desirable to synchronize the block after writing the register or in the case of a single field that spans across multiple registers. For instance, the NCO requires three 16-bit register writes to set the frequency. Upon writing the last of these registers an autosync is generated to deliver the entire field to the NCO block at once, rather than in pieces after each individual register write. For a field that spans multiple registers, all non-AUTOSYNC registers for the field must be written first before the actual AUTOSYNC register.
 - **No RESET Value:** These are NORMAL registers, but the reset value **cannot** be guaranteed. This could be because the register has some read_only bits or some internal logic partially controls the bit values.
- **READ_ONLY:** Registers that can be read from but not written to.
- **WRITE_TO_CLEAR:** These registers are just like NORMAL registers with one exception. They can be written and read, however, when the internal logic asynchronously sets a bit high in one of these registers, that bit stays high until it is written to '0'. This way interrupts will be captured and stay constant until cleared by the user. In the DAC39J82, register *config100-108* are WRTE_TO_CLEAR registers.

7.3.8 Multi-Device Synchronization

In many applications, such as multi-antenna systems where the various transmit channels information is correlated, it is required that the latency across the link is deterministic and multiple DAC devices are completely synchronized such that their outputs are phase aligned. The DAC39J82 achieves the deterministic latency using SYSREF (JESD204B Subclass 1).

SYSREF is generated from the same clock domain as DACCLK, and is sampled at the rising edges of the device clock. It can be periodic, single-shot or “gapped” periodic. After having resynchronized its local multiframe clock (LMFC) to SYSREF, the DAC will request a link re-initialization via SYNC interface. Processing of the signal on the SYSREF input can be enabled and disabled via the SPI interface.

7.3.9 Input Multiplexer

The DAC39J82 includes a multiplexer after the JESD204B interface that allows any input stream A-B to be routed to any signal channel A-B. See *pathx_in_sel* for details on how to configure the cross-bar switches.

7.3.10 FIR Filters

Figure 60 through Figure 63 show the magnitude spectrum response for the FIR0, FIR1, FIR2 and FIR3 interpolating filters where f_{IN} is the input data rate to the FIR filter. Figure 64 to Figure 67 show the composite filter response for 2x, 4x, 8x and 16x interpolation. The transition band for all interpolation settings is from 0.4 to $0.6 \times f_{DATA}$ (the input data rate to the device) with $< 0.001\text{dB}$ of pass-band ripple and $> 90\text{ dB}$ stop-band attenuation.

The DAC39J82 includes a no interpolation 1x mode. However, the input data rate in this mode is limited to 1230 MSPS. See more details in Table 10.

The DAC39J82 also has a 9-tap inverse sinc filter (FIR4) that runs at the DAC update rate (f_{DAC}) that can be used to flatten the frequency response of the sample-and-hold output. The DAC sample-and-hold output sets the output current and holds it constant for one DAC clock cycle until the next sample, resulting in the well-known $\sin(x)/x$ or sinc(x) frequency response (Figure 68, red line). The inverse sinc filter response (Figure 68, blue line) has the opposite frequency response from 0 to $0.4 \times f_{DAC}$, resulting in the combined response (Figure 68, green line). Between 0 to $0.4 \times f_{DAC}$, the inverse sinc filter compensates the sample-and-hold roll-off with less than 0.03 dB error.

The inverse sinc filter has a gain > 1 at all frequencies. Therefore, the signal input to FIR4 must be reduced from full scale to prevent saturation in the filter. The amount of back-off required depends on the signal frequency, and is set such that at the signal frequencies the combination of the input signal and filter response is less than 1 (0 dB). For example, if the signal input to FIR4 is at $0.25 \times f_{DAC}$, the response of FIR4 is 0.9 dB , and the signal must be backed off from full scale by 0.9 dB to avoid saturation. The gain function in the QMC blocks can be used to reduce the amplitude of the input signal. The advantage of FIR4 having a positive gain at all frequencies is that the user is then able to optimize the back-off of the signal based on its frequency.

The filter taps for all digital filters are listed in Table 14. Note that the loss of signal amplitude may result in lower SNR due to decrease in signal amplitude.

7.3.11 Full Complex Mixer

The DAC39J82 has a full complex mixer (FMIX) block with a Numerically Controlled Oscillator (NCO) that enables flexible frequency placement without imposing additional limitations in the signal bandwidth. The NCO has a 48-bit frequency register (***phaseaddab*** (47:0)) and 16-bit phase register (***phaseoffsetab*** (15:0)) that generate the sine and cosine terms for the complex mixing. The NCO block diagram is shown in [Figure 69](#).

Figure 69. NCO Block Diagram

Synchronization of the NCO occurs by resetting the NCO accumulator to zero. The synchronization source is selected by **syncsel_NCO** (3:0) in **config31**. The frequency word in the **phaseaddab** (47:0) register is added to the accumulator every clock cycle, f_{DAC} . The output frequency of the NCO is:

$$f_{NCO} = \frac{freq \times f_{NCO_CLK}}{2^{48}}$$

Treating the complex channel in the DAC39J82 as a complex vector of the form $I + jQ$, the output of FMIX $I_{OUT}(t)$ and $Q_{OUT}(t)$ is

$$I_{OUT}(t) = (I_{IN}(t)\cos(2\pi f_{NCO}t + \delta) - Q_{IN}(t)\sin(2\pi f_{NCO}t + \delta)) \times 2^{(mixer_gain - 1)}$$

$$Q_{OUT}(t) = (I_{IN}(t)\sin(2\pi f_{NCO}t + \delta) + Q_{IN}(t)\cos(2\pi f_{NCO}t + \delta)) \times 2^{(mixer_gain - 1)}$$

where t is the time since the last resetting of the NCO accumulator, δ is the phase offset value and $mixer_gain$ is either 0 or 1. δ is given by:

$$\delta = 2\pi \times phase_offsetAB(15:0)/2^{16}$$

A block diagram of the mixer is shown in Figure 70. The complex mixer can be used as a digital quadrature modulator with a real output simply by only using the I_{OUT} branch and ignoring the Q_{OUT} branch.

Figure 70. Complex Mixer Block Diagram

The maximum output amplitude of FMIX occurs if $I_{IN}(t)$ and $Q_{IN}(t)$ are simultaneously full scale amplitude and the sine and cosine arguments are equal to $2\pi \times f_{NCO}t + \delta (2N-1) \times \pi/4$ ($N = 1, 2, \dots$).

With **mixer_gain** = 0 in *config2*, the gain through FMIX is $\sqrt{2}/2$ or –3 dB. This loss in signal power is in most cases undesirable, and it is recommended that the gain function of the QMC block be used to increase the signal by 3 dB to compensate. With **mixer_gain** = 1, the gain through FMIX is $\sqrt{2}$ or +3 dB, which can cause clipping of the signal if $I_{IN}(t)$ and $Q_{IN}(t)$ are simultaneously near full scale amplitude and should therefore be used with caution.

7.3.12 Coarse Mixer

In addition to the full complex mixer the DAC39J82 also has a coarse mixer block capable of shifting the input signal spectrum by the fixed mixing frequencies $\pm n \times f_s/8$. Using the coarse mixer instead of the full mixer will result in lower power consumption.

Treating the complex channel as a complex vector of the form $I(t) + j Q(t)$, the outputs of the coarse mixer, $I_{OUT}(t)$ and $Q_{OUT}(t)$ are equivalent to:

$$I_{OUT}(t) = I(t)\cos(2\pi f_{CMIX}t) - Q(t)\sin(2\pi f_{CMIX}t)$$

$$Q_{OUT}(t) = I(t)\sin(2\pi f_{CMIX}t) + Q(t)\cos(2\pi f_{CMIX}t)$$

where f_{CMIX} is the fixed mixing frequency selected by **cmix**=(fs8, fs4, fs2, fsm4). The mixing combinations are described in [Table 13](#).

Table 13. Coarse Mixer Combinations

cmix(3:0)	Fs/8 MIXER cmix(3)	Fs/4 MIXER cmix(2)	Fs/2 MIXER cmix(1)	-Fs/4 MIXER cmix(0)	MIXING MODE

All others	—	—	—	—	Not recommended

7.3.13 Dithering

The DAC39J82 supports the addition of a band limited dither to the DAC output after the complex mixer. This feature is enabled by set **dither_ena** to “1” and can be useful in reducing the high order harmonics. The generated dithering sequence can be optionally up-converted to an offset of $F_s/2$ by setting **dither_mixer_ena** to “1”. The added dithering sequence has variable amplitude in 6 dB steps via **dither_sra_sel**.

7.3.14 Quadrature Modulation Correction (QMC)

7.3.14.1 Gain and Phase Correction

The DAC39J82 includes a Quadrature Modulator Correction (QMC) block. The QMC blocks provide a mean for changing the gain and phase of the complex signals to compensate for any I and Q imbalances present in an analog quadrature modulator. The block diagram for the QMC block is shown in [Figure 71](#). The QMC block contains 3 programmable parameters.

Registers **mem_qmc_gaina** (10:0) and **mem_qmc_gainb** (10:0) controls the I and Q path gains and is an 11-bit unsigned value with a range of 0 to 1.9990 and the default gain is 1.0000. The implied decimal point for the multiplication is between bit 9 and bit 10. The resolution allows suppression to > 65 dBc for a frequency independent IQ imbalance (the fine delay FIR block also contains gain control through the filter taps or inverse gain block that allows control with > 20 bits resolution, which can be used to improve the sideband suppression).

Register **mem_qmc_phaseab** (11:0) control the phase imbalance between I and Q and are a 12-bit values with a range of –0.5 to approximately 0.49975. The QMC phase term is not a direct phase rotation but a constant that is multiplied by each “Q” sample then summed into the “I” sample path. This is an approximation of a true phase rotation in order to keep the implementation simple. The resolution of the phase term allows suppression to > 80 dBc for a frequency independent IQ imbalance.

LO feed-through can be minimized by adjusting the DAC offset feature described below.

Figure 71. QMC Block Diagram

7.3.14.2 Offset Correction

Registers **mem_qmc_offseta** (12:0) and **mem_qmc_offsetb** (12:0) can be used to independently adjust the DC offsets of each channel. The offset values are represented in 2s-complement format with a range from –4096 to 4095. The LSB resolution of the offset allows LO suppression to better than 90 dBFS.

The offset value adds a digital offset to the digital data before digital-to-analog conversion. Since the offset is added directly to the data it may be necessary to back off the signal to prevent saturation. Both data and offset values are LSB aligned.

Figure 72. Digital Offset Block Diagram

7.3.15 Group Delay Correction Block

A complex transmitter system typically consists of a DAC, reconstruction filter network, and I/Q modulator. Besides the gain and phase mismatch contribution, there could also be timing mismatch contribution from each component. For instance, the timing mismatch could come from the PCB trace length variation between the I and Q channels and the group delay variation from the reconstruction filter. This timing mismatch in the complex transmitter system creates phase mismatch that varies linearly with respect to frequency. To compensate for the I/Q imbalances due to this mismatch, the DAC39J82 has group delay correction block for each DAC channel.

The DAC39J82 incorporates a FIR filter for small fractional group delay and 2 FIR filters for large fractional group delay. The input data to this block consists of a complex data (I/Q) channel i.e. 2 buses of 16-bit data. Control bits from configuration registers select the data path for all inputs through this block. Each input can either go through the small fractional delay filter (while its conjugate part goes through the matched delay line) or bypass the small fractional delay sub-block completely (matched delay line is bypassed for the conjugate part). The input to the large fractional delay F can either come from the output of small fractional delay sub-block or the original input to the block. The large fractional delay sub-block can also be completely bypassed if desired.

The DAC39J82 also include an integer delay block following each large fractional group delay filter, which can further delay the DAC output by $[0-3] \times T_{dac}$. Channel A&B share the same control signal **output_delayab**, and channel C&D share the same control signal **output_delaycd**, which means that channel A&B have the same integer delay, and channel C&D have the same integer delay.

Figure 73. Diagram of Group Delay Correction

7.3.15.1 Fine Fractional Delay FIR Filter

The coefficients of the FIR filters for small fractional delay are programmable to user defined values which allows users to implement their own filter transfer functions. Filter designs supporting group delay variation in the range $[0.002 \text{ } 0.198] \times T_{dac}$, where T is the time period of DAC Clock, is listed in [Table 15](#). The bit widths of all coefficients are fixed, which puts limits on the range of values each coefficient can acquire.

7.3.15.2 Coarse Fractional Delay FIR Filter

The coefficients of FIR filters for large fractional delay can only be chosen from a predefined set of values. Each set of values produces a specific delay with a step of $1/8 \times T_{dac}$. The value of coefficients as well as their resultant fractional delay is provided in [Table 16](#).

Table 16. Available Coefficient Sets for Large Fractional Delay FIR

7.3.16 Output Multiplexer

The DAC39J82 provides four analog outputs and includes an output multiplexer before the digital to analog converters that allows any signal channel to be routed to any analog outputs. See **pathx_out_sel** for details on how to configure the cross-bar switches.

7.3.17 Power Measurement And Power Amplifier Protection

The DAC39J82 provides an optional mechanism to protect the Power Amplifier (PA) in cases when the signal power shows some abnormality. For example, if the data clock is lost, the FIFO would automatically generate a single tone signal, which causes abnormally high average power and could be dangerous to the PA. In the PA protection mechanism, the signal power is monitored by maintaining a sliding window accumulation of last N samples. N is selectable to be 64 or 128 based on the setting of *pap_dlylen_sel*. The average amplitude of input signal is computed by dividing accumulated value by the number of samples in the delay-line (N). The result is then compared against a threshold (*pap_vth*). If the threshold is violated, the delayed input signal is divided by a value chosen by *pap_gain*, to form a scaled down version of the input signal. Since PAP output derives from a delay-line, there is deterministic latency of at least N cycles from the block input to block output. The PA protection is enabled by setting the *pap_ena* bit to “1”.

Figure 74. Diagram of Power Measurement and PA Protection Mechanism

7.3.18 Serdes Test Modes

The DAC39J82 supports a number of basic pattern generation and verification of SerDes via SIF. Three pseudo random bit stream (PRBS) sequences are available, along with an alternating 0/1 pattern and a 20-bit user-defined sequence. The 2^7-1 , $2^{31}-1$ or $2^{23}-1$ sequences implemented can often be found programmed into standard test equipment, such as a Bit Error Rate Tester (BERT). Pattern generation and verification selection is via the **TESTPATT** fields of *rw_cfg_rx0*[14:12], as shown in [Table 17](#).

Table 17. SerDes Test Pattern Selection

TESTPATT	EFFECT
000	Test mode disabled.
001	Alternating 0/1 Pattern. An alternating 0/1 pattern with a period of 2UI.
010	Generate or Verify 2^7-1 PRBS. Uses a 7-bit LFSR with feedback polynomial $x^7 + x^6 + 1$.
011	Generate or Verify $2^{23}-1$ PRBS. Uses an ITU O.150 conformant 23-bit LFSR with feedback polynomial $x^{23} + x^{18} + 1$.
100	Generate or Verify $2^{31}-1$ PRBS. Uses an ITU O.150 conformant 31-bit LFSR with feedback polynomial $x^{31} + x^{28} + 1$.
101	User-defined 20-bit pattern. Uses the USR PATT IEEE1500 Tuning instruction field to specify the pattern. The default value is 0x666666.
11x	Reserved

Pattern verification compares the output of the serial to parallel converter with an expected pattern. When there is a mismatch, the **TESTFAIL** bit is driven high, which can be programmed to come out the ALARM pin by setting **dtest[3:0]** to “0011”.

The DAC39J82 also provide a number of advanced diagnostic capabilities controlled by the IEEE 1500 interface. These are:

- Accumulation of pattern verification errors;
- The ability to map out the width and height of the receive eye, known as Eye Scan;
- Real-time monitoring of internal voltages and currents;

The SerDes blocks support the following IEEE1500 instructions:

Table 18. IEEE1500 Instruction for SerDes Receivers

INSTRUCTION	OPCODE	DESCRIPTION
ws_bypass	0x00	Bypass. Selects a 1-bit bypass data register. Use when accessing other macros on the same IEEE1500 scan chain.
ws_cfg	0x35	Configuration. Write protection options for other instructions.
ws_core	0x30	Core. Fields also accessible via dedicated core-side ports.
ws_tuning	0x31	Tuning. Fields for fine tuning macro performance.
ws_debug	0x32	Debug. Fields for advanced control, manufacturing test, silicon characterization and debug
ws_unshadowed	0x34	Unshadowed. Fields for silicon characterization.
ws_char	0x33	Char. Fields used for eye scan.

The data for each SerDes instruction is formed by chaining together sub-components called head, body (receiver or transmitter) and tail. The DAC39J82 uses two SerDes receiver blocks R0 and R1, each of which contains 4 receive lanes (channels), the data for each IEEE1500 instruction is formed by chaining **{head, receive lane 0, receive lane 1, receive lane 2, receive lane 3, tail}**. A description of bits in head, body and tail for each instruction is given as follows:

NOTE

All multi-bit signals in each chain are packed with bits reversed e.g. mpy[7:0] in ws_core head subchain is packed as {retime, enpll, mpy[0:7], vrange, lb[0:1]}. All DATA REGISTER READS from SerDes Block R0 should read 1 bit more than the desired number of bits and discard the first bit received on TDO e.g., to read 40-bit data from R0 block, 41 bits should be read off from TDO and the first bit received should be discarded. Similarly, any data written to SerDes Block R0 Data Registers should be prefixed with an extra 0.

FIELD	DESCRIPTION
RETIME	No function.
CHAIN LENGTH = 194 BITS	

7.3.19 Error Counter

All receive channels include a 12-bit counter for accumulating pattern verification errors. This counter is accessible via the ECOUNT IEEE1500 Char field. It is an essential part of the eye scan capability (see next section), though can be used independently of this..

The counter increments once for every cycle that the TESTFAIL bit is detected. The counter will not increment when at its maximum value (i.e., all 1s). When an IEEE1500 capture is performed, the count value is loaded into the ECOUNT scan elements (so that it can be scanned out), and the counter is then reset, provided ENCOR is set high.

ECOUNT can be used to get a measure of the bit error rate. However, as the error rate increases, it will become less accurate due to limitations of the pattern verification capabilities. Specifically, the pattern verifier checks multiple bits in parallel (as determined by the Rx bus width), and it is not possible to distinguish between 1 or more errors in this.

7.3.20 Eye Scan

All receive channels provide features which facilitate mapping the received data eye or extracting a symbol response. A number of fields accessible via the IEEE1500 Char scan chain allow the required low level data to be gathered. The process of transforming this data into a map of the eye or a symbol response must then be performed externally, typically in software.

The basic principle used is as follows:

- Enable dedicated eye scan input samplers, and generate an error when the value sampled differs from the normal data sample;
- Apply a voltage offset to the dedicated eye scan input samplers, to effectively reduce their sensitivity;
- Apply a phase offset to adjust the point in the eye that the dedicated eye scan data samples are taken;
- Reset the error counter to remove any false errors accumulated as a result of the voltage or phase offset adjustments;
- Run in this state for a period of time, periodically checking to see if any errors have occurred;
- Change voltage and/or phase offset, and repeat.

Alternatively, the algorithm can be configured to optimize the voltage offset at a specified phase offset, over a specified time interval.

Eye scan can be used in both synchronous and asynchronous systems, while receiving normal data traffic. The IEEE1500 Char fields used to directly control eye scan and symbol response extraction are ES, ESWORD, ES BIT SELECT, ESLEN, ESPO, ESVO, ESVO OVR, ESRUN and ESDONE, see [Table 22](#). Eye scan errors are accumulated in ECOUNT.

The required eyescan mode is selected via the ES field, as shown in [Table 23](#). When enabled, only data from the bit position within the 20-bit word specified via ES BIT SELECT is analyzed. In other words, only eye scan errors associated with data output at this bit position will accumulate in ECOUNT. The maximum legal ES BIT SELECT is 10011.

Table 23. Eye Scan Mode Selection

ES[3:0]	EFFECT
0000	Disabled. Eye scan is disabled.
0x01	Compare. Counts mismatches between the normal sample and the eye scan sample if ES[2] = 0, and matches otherwise.
0x10	Compare zeros. As ES = 0x01, but only analyses zeros, and ignores ones.
0x11	Compare ones. As ES = 0x01, but only analyses ones, and ignores zeroes
0100	Count ones. Increments ECOUNT when the eye scan sample is a 1.
1x00	Average. Adjusts ESVO to the average eye opening over the time interval specified by ESLEN. Analyses zeroes when ES[2] = 0, and ones when ES[2] = 1.

Table 23. Eye Scan Mode Selection (continued)

ES[3:0]	EFFECT
1001 1110	Outer. Adjusts ESVO to the outer eye opening (i.e. lowest voltage zero, highest voltage 1) over the time interval specified by ESLEN. 1001 analyses zeroes, 1110 analyses ones.
1010 1101	Inner. Adjusts ESVO to the inner eye opening (i.e. highest voltage zero, lowest voltage 1) over the time interval specified by ESLEN. 1010 analyses zeroes, 1101 analyses ones.
1x11	Timed Compare. As ES = 001x, but analyses over the time interval specified by ESLEN. Analyses zeroes when ES[2] = 0, and ones when ES[2] = 1.

When ES[3] = 0, the selected analysis runs continuously. However, when ES[3] = 1, only the number of qualified samples specified by ESLEN, as shown in [Table 24](#). In this case, analysis is started by writing a 1 to ESRUN (it is not necessary to set it back to 0). When analysis completes, ESDONE will be set to 1.

Table 24. Eye Scan Run Length

ESLen	NUMBER OF SAMPLES ANALYZED
00	127
01	1023
10	8095
11	65535

When ESVO OVR = 1, the ESVO field determines the amount of offset voltage that is applied to the eye scan data samplers associated with rxpi and rxni. The amount of offset is variable between 0 and 300 mV in increments of ~10 mV, as shown in [Table 25](#). When ES[3] = 1, ESVO OVR must be 0 to allow the optimized voltage offset to be read back via ESVO.

Table 25. Eye Scan Voltage Offset

ESVO	OFFSET (mV)
100000	–310
..	..
111110	–20
111111	–10
000000	0
000001	10
000010	20
..	..
011111	300

The phase position of the samplers associated with rxpi and rxni, is controlled to a precision of 1/32UI. When ES is not 00, the phase position can be adjusted forwards or backwards by more than one UI using the ESPO field, as shown in [Table 26](#). In normal use, the range should be limited to ±0.5UI (+15 to –16 phase steps).

Table 26. Eye Scan Phase Offset

ESPO	OFFSET (1/32UI)
011111	+63
..	..
000001	+1
000000	0
111111	–1
..	..
100000	–64

7.3.21 JESD204B Pattern Test

The DAC39J82 supports the following test patterns for JESD204B:

- Link layer test pattern
 - Verify repeating /D.21.5/ high frequency pattern for random jitter (RJ)
 - Verify repeating /K.28.5/ mixed frequency pattern for deterministic jitter (DJ)
 - Verify repeating initial lane alignment (ILA) sequence
 - RPAT, JSPAT or JTSPAT pattern can be verified using errors counter of 8b/10b errors produced over an amount of time to get an estimate of BER.
- Transport layer test pattern: implements a short transport layer pattern check based on F = 1,2,4 or 8. The short test pattern has a duration of one frame period and is repeated continuously for the duration of the test. Refer to JESD204B standard section 5.1.6 for more details.
 - F = 1 : Looks for a constant 0xF1.
 - F = 2 : Each frame should consist of 0xF1, 0xE2
 - F = 4 : Looks for a constant 0xF1, 0xE2, 0xD3, 0xC4
 - F = 8 : Each frame should consist of 0xF1, 0xE2, 0xD3, 0xC4, 0xB5, 0xA6, 0x97, 0x80

Users can select to output the internal data (ex, the 8b/10 decoder output, comma alignment output, lane alignment output, frame alignment output, descrambler output, etc) of a JESD link for test purpose. See [*jesd_testbus_sel*](#) for configuration details.

7.3.22 Temperature Sensor

The DAC39J82 incorporates a temperature sensor block which monitors the temperature by measuring the voltage across 2 transistors. The voltage is converted to an 8-bit digital word using a successive-approximation (SAR) analog to digital conversion process. The result is scaled, limited and formatted as a twos complement value representing the temperature in degrees Celsius.

The sampling is controlled by the serial interface signals SDENB and SCLK. If the temperature sensor is enabled (**tsense_sleep** = "0" in register *config26*) a conversion takes place each time the serial port is written or read. The data is only read and sent out by the digital block when the temperature sensor is read in **memin_tempdata** in *config7*. The conversion uses the first eight clocks of the serial clock as the capture and conversion clock, the data is valid on the falling eighth SCLK. The data is then clocked out of the chip on the rising edge of the ninth SCLK. No other clocks to the chip are necessary for the temperature sensor operation. As a result the temperature sensor is enabled even when the device is in sleep mode.

In order for the process described above to operate properly, the serial port read from *config6* must be done with an SCLK period of at least 1 μ s. If this is not satisfied the temperature sensor accuracy is greatly reduced.

7.3.23 Alarm Monitoring

The DAC39J82 includes a flexible set of alarm monitoring that can be used to alert of a possible malfunction scenario. All the alarm events can be accessed either through the SIP registers and/or through the ALARM pin. Once an alarm is set, the corresponding alarm bit in register *configtbd* must be reset through the serial interface to allow further testing. The set of alarms includes the following conditions:

- **JESD alarms**
 - multiframe alignment_error. Occurs when multiframe alignment fails.
 - frame alignment error. Occurs when multiframe alignment fails.
 - link configuration error. Occurs when configuration data in ILA sequence does not match programmed configuration.
 - elastic buffer overflow. Occurs when bad RBD value is used causing the elastic buffer to overflow.
 - elastic buffer match error. Occurs when the first non-/K/ doesn't match the programmed character.
 - code synchronization error.
 - 8b/10b not-in-table decode error.
 - 8b/10 disparity error.
 - alarm_from_shorttest. Occurs when the JESD204B interface fails the short pattern test.
- **SerDes alarms**
 - memin_rw_losdct. Occurs when there are loss of signal detect from SerDes lanes.

- FIFO write error. Occurs if write request and FIFO is full.
- FIFO write full: Occurs if FIFO is full.
- FIFO read error. Occurs if read request and FIFO is empty.
- FIFO read empty: Occurs if FIFO is empty.
- alarm_rw0_pll. Occurs if the PLL in the SerDes block for RX0 through RX3 goes out of lock.
- alarm_rw1_pll. Occurs if the PLL in the SerDes block for RX4 through RX7 goes out of lock.
- **SYSREF alarm**
 - alarm_sysref_err. Occurs when the SYSREF is received at an unexpected time. If too many of these occur it will cause the JESD to go into synchronization mode again.
- **DAC PLL alarm**
 - alarm_from_pll. Occurs when the DAC PLL is out of lock. This alarm can be ignored if the DAC PLL is not being used.
- **PAP alarms**
 - alarm_pap. Occurs when the average power is above the threshold. While any alarm_pap is asserted the attenuation for the appropriate data path is applied.

7.3.24 LVPECL Inputs

Figure 75 shows an equivalent circuit for the DAC input clock (DACCLKP/N) and the SYSREF (SYSREFP/N).

Figure 75. DACCLKP/N and SYSREFP/N Equivalent Input Circuit

7.3.25 CMOS Digital Inputs

Figure 76 shows a schematic of the equivalent CMOS digital inputs of the DAC39J82. SDIO, SCLK, TCLK, SLEEP, TESTMODE and TXENABLE have pull-down resistors while SDENB, RESETB, TMS, TDI and TRSTB have pull-up resistors internal to the DAC39J82. See the specification table for logic thresholds. The pull-up and pull-down circuitry is approximately equivalent to 100 kΩ.

Figure 76. CMOS Digital Equivalent Input

7.3.26 Reference Operation

The DAC39J82 uses a bandgap reference and control amplifier for biasing the full-scale output current. The full-scale output current is set by applying an external resistor R_{BIAS} to pin BIASJ. The bias current I_{BIAS} through resistor R_{BIAS} is defined by the on-chip bandgap reference voltage and control amplifier. The default full-scale output current equals 64 times this bias current and can thus be expressed as:

$$IOUT_{FS} = 16 \times I_{BIAS} = 64 \times V_{EXTIO} / R_{BIAS}$$

The DAC39J82 has a 4-bit coarse gain control *coarse_dac(3:0)* in the *configtbd* register. Using gain control, the $IOUT_{FS}$ can be expressed as:

$$IOUT_{FS} = (coarse_dac + 1) / 16 \times I_{BIAS} \times 64 = (coarse_dac + 1) / 16 \times V_{EXTIO} / R_{BIAS} \times 64$$

where V_{EXTIO} is the voltage at pin EXTIO. The bandgap reference voltage delivers an accurate voltage of 0.9V. This reference is active when *extref_ena* = '0' in *configtbd*. An external decoupling capacitor C_{EXT} of 0.1 μ F should be connected externally to pin EXTIO for compensation. The bandgap reference can additionally be used for external reference operation. In that case, an external buffer with high impedance input should be applied in order to limit the bandgap load current to a maximum of 100 nA. The internal reference can be disabled and overridden by an external reference by setting the *extref_ena* control bit. Capacitor C_{EXT} may hence be omitted. Pin EXTIO thus serves as either input or output node.

The full-scale output current can be adjusted from 30 mA down to 10 mA by varying resistor R_{BIAS} or changing the externally applied reference voltage.

7.3.27 Analog Outputs

The CMOS DACs consist of a segmented array of PMOS current sources, capable of sourcing a full-scale output current up to 30 mA. Differential current switches direct the current to either one of the complimentary output nodes IOUTP or IOUTN. Complimentary output currents enable differential operation, thus canceling out common mode noise sources (digital feed-through, on-chip and PCB noise), dc offsets, even order distortion components, and increasing signal output power by a factor of four.

The full-scale output current is set using external resistor R_{BIAS} in combination with an on-chip bandgap voltage reference source (+0.9 V) and control amplifier. Current I_{BIAS} through resistor R_{BIAS} is mirrored internally to provide a maximum full-scale output current equal to 16 times I_{BIAS} .

The relation between IOUTP and IOUTN can be expressed as:

$$IOUT_{FS} = IOUTP + IOUTN$$

We will denote current flowing into a node as –current and current flowing out of a node as +current. Since the output stage is a current source the current flows from the IOUTP and IOUTN pins. The output current flow in each pin driving a resistive load can be expressed as:

$$IOUTP = IOUT_{FS} \times CODE / 65536$$

$$IOUTN = IOUT_{FS} \times (65535 - CODE) / 65536$$

where CODE is the decimal representation of the DAC data input word.

For the case where IOUTP and IOUTN drive resistor loads R_L directly, this translates into single ended voltages at IOUTP and IOUTN:

$$VOUTP = IOUT1 \times R_L$$

$$VOUTN = IOUT2 \times R_L$$

Assuming that the data is full scale (65535 in offset binary notation) and the R_L is 25 Ω , the differential voltage between pins IOUTP and IOUTN can be expressed as:

$$VOUTP = 20mA \times 25 \Omega = 0.5 V$$

$$VOUTN = 0mA \times 25 \Omega = 0 V$$

$$VDIFF = VOUTP - VOUTN = 0.5 V$$

Note that care should be taken not to exceed the compliance voltages at node IOUTP and IOUTN, which would lead to increased signal distortion.

7.3.28 DAC Transfer Function

The DAC39J82 can be easily configured to drive a doubly terminated 50 Ω cable using a properly selected RF transformer. Figure 77 and Figure 78 show the 50 Ω doubly terminated transformer configuration with 1:1 and 4:1 impedance ratio, respectively. Note that the center tap of the primary input of the transformer has to be grounded to enable a DC current flow. Applying a 20-mA full-scale output current would lead to a 0.5 V_{pp} for a 1:1 transformer and a 1-V_{pp} output for a 4:1 transformer. The low dc-impedance between IOUTP or IOUTN and the transformer center tap sets the center of the ac-signal to GND, so the 1-V_{pp} output for the 4:1 transformer results in an output between –0.5 V and +0.5 V.

Figure 77. Driving a Doubly Terminated 50- Ω Cable Using a 1:1 Impedance Ratio Transformer

Figure 78. Driving a Doubly Terminated 50- Ω Cable Using a 4:1 Impedance Ratio Transformer

7.4 Device Functional Modes

7.4.1 Clocking Modes

The DAC39J82 has a single differential clock DACCLKN/P to clock the DAC cores and internal digital logic. The DAC39J82 DACCLK can be sourced directly or generated through an on-chip low-jitter phase-locked loop (PLL).

In those applications requiring extremely low noise it is recommended to bypass the PLL and source the DAC clock directly from a high-quality external clock to the DACCLK input. In most applications system clocking can be simplified by using the on-chip PLL to generate the DAC core clock while still satisfying performance requirements. In this case the DACCLK pins are used as the reference frequency input to the PLL.

7.4.1.1 PLL Bypass Mode

In PLL bypass mode a high quality clock is sourced to the DACCLK inputs. This clock is used to directly clock the DAC39J82 DAC cores. This mode gives the device best performance and is recommended for extremely demanding applications.

Device Functional Modes (continued)

The bypass mode is selected by setting the following:

1. **pll_ena** bit in register *config49* to “0” to bypass the PLL circuitry.
2. **pll_sleep** bit in register *config26* to “1” to put the PLL and VCO into sleep mode.

7.4.1.2 PLL Mode

In this mode the clock at the DACCLK input functions as a reference clock source to the on-chip PLL. The on-chip PLL will then multiply this reference clock to supply a higher frequency DAC cores clock. Figure 79 shows the block diagram of the PLL circuit, where N divider ratio ranges from 1 to 32, M divider ratio ranges from 1 to 256, and VCO prescaler divider from 2 to 18.

Figure 79. PLL Block Diagram

The DAC39J82 PLL mode is selected by setting the following:

1. **pll_ena** bit in register *config49* to “1” to route to the PLL and clock path.
2. **pll_sleep** bit in register *config26* to “0” to enable the PLL and VCO.

The output frequency of the VCO covers two frequency spans: H-band (4.44–5.6 GHz) and L-band (3.7–4.66 GHz). When **pll_vcose1** in register *config51* is “1”, the L-band is selected; when **pll_vcose1** is “0”, the H-band is selected. At each band, the VCO range can be further adjusted by using the 6-bits **pll_vco** in register *config51*. Figure 80 shows a typical relationship between the PLL VCO coarse tuning bits **pll_vco** and the VCO center frequency. The corresponding equations for the H-band and L-band VCO are given in Equation 1 and Equation 2, respectively. Note that It is recommended to shift **pll_vco** by +1 to ensure the VCO operation at hot temp environment. In case of cold temp environment, shift by -1 on the variable **pll_vco** is recommended.

$$\text{H-Band: VCO Frequency (MHz)} = 0.10998 \cdot \text{pll_vco}^2 + 10.574 \cdot \text{pll_vco} + 4446.3, \quad (1)$$

where **pll_vcose1** = “0” and **pll_vcoitune** = “11”.

$$\text{L-Band: VCO Frequency (MHz)} = 0.089703 \cdot \text{pll_vco}^2 + 8.8312 \cdot \text{pll_vco} + 3752.5, \quad (2)$$

where **pll_vcose1** = “1” and **pll_vcoitune** = “10”.

Device Functional Modes (continued)

Figure 80. Typical PLL VCO Center Frequency vs Coarse Tuning Bits

Common wireless infrastructure frequencies are generated from this VCO frequency in conjunction with the pre-scaler setting **pll_p** in register *config50* as shown in Table 27. When there are multiple valid VCO frequency and the pre-scaler settings to generate the same desired DACCLK frequency, higher pre-scaler divider ratio is recommended for better phase noise performance.

Table 27. VCO Operation

VCO FREQUENCY (MHz)	pll_vcose1	PRE-SCALE DIVIDER	DESIRED DACCLK (MHz)	pll_p(3:0)
4915.2	0	2	2457.6	0000
3932.16	1	2	1966.08	0000
4423.68	1	3	1474.56	0001
4915.2	0	4	1228.8	0010
4915.2	0	5	983.04	0011
5160.96	0	7	737.28	0101
4915.2	0	8	614.4	0110
4915.2	0	10	491.52	0111

The M divider is used to determine the phase-frequency-detector (PFD) and charge-pump (CP) frequency.

Table 28. PFD and CP Operation

DACCLK FREQUENCY (MHz)	M DIVIDER	PFD UPDATE RATE (MHz)	pll_m(7:0)
1474.56	12	122.88	00001011
1474.56	24	61.44	00010111
1474.56	48	30.72	00101111
1474.56	64	15.36	00111111

The N divider in the loop allows the PFD to operate at a lower frequency than the reference clock.

The overall divide ratio inside the loop is the product of the Pre-Scale and M dividers ($P \cdot M$). The 5-bit *pll_cp_adj* is to set the charge pump current from 0 to 1.55 mA with a step of 50 μ A. In nominal condition, if vco runs at 5 GHz with P-ratio and M-ratio set as 2 and 4, the DACCLK frequency would be 2.5GHz and PFD frequency 625 MHz. This needs 600 μ A charge pump current to stabilize the loop and gives the optimized phase noise performance. When $P \cdot M$ ratio increases, the charge pump current needs to be increased accordingly to sustain enough phase margin for the loop. By tuning the charge pump current, a wide range of PM ratio can be supported with the internal loop filter. In very extreme cases when the $P \cdot M$ ratio is huge (ex. PFD frequency of 10 MHz, VCO frequency of 4 GHz) and the loop cannot be stabilized even with the largest charge pump current, an external loop filter is required.

7.4.2 PRBS Test Mode

The DAC39J82 supports three types of PRBS sequences (2^7-1 , $2^{23}-1$, and $2^{31}-1$) to verify the SerDes via SIF. To run the PRBS test on the DAC, users first need to setup the DAC for normal use, then make the following SPI writes:

1. *config74*, set bits 4:0 to 0x1E to disable JESD clock.
2. *config61*, set bits 14:12 to 0x2 to enable the 7-bit PRBS test pattern; or set bits 14:12 to 0x3 to enable the 23-bit PRBS test pattern; or set bits 14:12 to 0x4 to enable the 31-bit PRBS test pattern.
3. *config27*, set bits 11:8 to 0x3 to output PRBS testfail on ALARM pin.
4. *config27*, set bits 14:12 to the lane to be tested (0 through 7).
5. *config62*, make sure bits 12:11 are set to 0x0 to disable character alignment.

Users should monitor the ALARM pin to see the results of the test. If the test is failing, ALARM will be high (or toggling if marginal). If the test is passing, the ALARM will be low.

Table 30. config0 Register Field Descriptions

Register Name	Addr (Hex)	Bit	Name	Function	Default Value
config0	0x0	15	qmc_offsetab_ena	Enable the offset function for the AB data path when asserted.	0
		14	reserved	reserved	0
		13	qmc_corrab_ena	Enable the Quadrature Modulator Correction (QMC) function for the AB data path when asserted.	0
		12	reserved	reserved	0
		11:08	interp	Determines the interpolation amount. 0000: 1x 0001: 2x 0010: 4x 0100: 8x 1000: 16x	0010
		7	alarm_zeros_txenable_ena	When asserted any alarm that isn't masked will mid-level the DAC output.	0
		6	reserved	reserved	0
		5	alarm_zeros_jesd_data_ena	When asserted any alarm that isn't masked will zero the data coming out of the JESD block.	0
		4	alarm_out_ena	When asserted the pin ALARM becomes an output instead of a tri-stated pin.	1
		3	alarm_out_pol	This bit changes the polarity of the ALARM signal. (0=negative logic, 1=positive logic)	1
		2	pap_ena	Turns on the Power Amp Protection (PAP) logic.	0
		1	inv_sinc_ab_ena	Turns on the inverse sinc filter for the AB path when programmed to '1'.	0
		0	reserved	reserved	0

7.5.1.2 config1 Register – Address: 0x01, Default: 0x0003

Table 32. config2 Register Field Descriptions

Register Name	Addr (Hex)	Bit	Name	Function	Default Value
config2	0x2	15:14	dac_bitwidth	Determines the bit width of the DAC. 00 : 16 bits 01 : 14 bits 10 : 16 bits 11 : 12 bits	00
		13	zero_invalid_data	Zero the data from the JESD block when the link is not established.	1
		12	shorttest_ena	Turns on the short test pattern of the JESD interface.	0
		11	reserved	Reserved	0
		10	reserved	Reserved	0
		9	reserved	Reserved	0
		8	reserved	Reserved	0
		7	sif4_ena	When asserted the SIF interface becomes a 4 pin interface. This bit has a lower priority than the dieid_ena bit.	0
		6	mixer_ena	When set high, the mixer block is turned on.	0
		5	mixer_gain	Add 6dB of gain to the mixer output when asserted.	0
		4	nco_ena	When set high, the full NCO block is turned on. This is not necessary for the fs/2, fs/4, -fs/4 and fs/8 modes.	0
		3	reserved	Reserved	0
		2	reserved	Reserved	0
		1	twos	When asserted, this bit tells the chip to presume that 2's complement data is arriving at the input. Otherwise offset binary is presumed.	1
		0	sif_reset	A transition from 0->1 causes a reset of the SIF registers. This bit is self clearing. This bit cannot take the place of the RESETB pin during powerup.	0

7.5.1.4 config3 Register – Address: 0x03, Default: 0xF380

pll_n					memin_pll_lfvolt		

Table 79. config49 Register Field Descriptions

Register Name	Addr (Hex)	Bit	Name	Function	Default Value
config49	0x31	15:13	lockdet_adj	Adjusts the sensitivity of the DAC PLL lock detector; 4 settings from 000 to 011. The 011 setting has the widest lock detection window, tolerating more jitter while reporting a lock. The 000 setting has a narrow window and will indicate an unlocked state more often.	000
		12	pll_reset	When set, the M divider, N divider and PFD are held reset.	0
		11	pll_ndivsync_ena	When on, the SYSREF input is used to sync the N dividers of the PLL.	0
		10	pll_ena	Enables the PLL output as the DAC clock when set; the clock provided at the DACCLKP/N is used as the PLL reference clock. When cleared, the PLL is bypassed and the clock provided at the DACCLKP/N pins is used as the DAC clock	0 FUSE controlled
		9:8	pll_cp	Must be set to 00 for proper PLL operation	00
		7:3	pll_n	Reference clock divider; divide by is N+1	00000
		2:0	memin_pll_lfvolt	Indicates the loop filter voltage; 111 is max, 000 is min. When the PLL is correctly programmed, this will read 011 or 100 for a centered loop filter voltage.	000 READ ONLY

Table 104. config74 Register Field Descriptions

Register Name	Addr (Hex)	Bit	Name	Function	Default Value
config74	0x4A	15:8	lane_ena	Turn on each SerDes lane as needed. Signal is active high. bit15 : SerDes lane7 enable bit14 : SerDes lane6 enable bit13 : SerDes lane5 enable bit12 : SerDes lane4 enable bit11 : SerDes lane3 enable bit10 : SerDes lane2 enable bit9 : SerDes lane1 enable bit8 : SerDes lane0 enable	0x00
		7:6	jesd_test_seq	Set to select and verify link layer test sequences. The error for these sequences comes out the lane alarms bit0. 1= fail and 0 = pass. 00 : test sequence disabled 01 : verify repeating D.21.5 high frequency pattern for random jitter 10 : verify repeating K.28.5 mixed frequency pattern for deterministic jitter 11 : verify repeating ILA sequence	00
		5	dual	Turn on "DUAL DAC" mode. This disables the clocks to the C and D data paths, reducing the power of the DIG block.	0
		4:1	init_state	Put the JESD block into "INIT_STATE" mode when high. During this mode the JESD can be programmed and its outputs will stay at zero. NOTE: See the JESD description of the correct startup sequence.	1111
		0	jesd_reset_n	Reset the JESD block when low. NOTE: See the JESD description of the correct startup sequence.	0

7.5.1.76 config75 Register – Address: 0x4B, Default: 0x0000

8 Applications and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The DAC39J82 is a 16-bit DAC with max input data rate up to 1.4GSPS per DAC. It provides one transmit paths with up to 1.12GHz complex information bandwidth. The DAC39J82 consumes about 1.1W at 2.8GSPS. The digital Quadrature Modulator Correction and Group Delay Correction enable complete IQ compensation for gain, offset, phase, and group delay between channels in direct up-conversion applications. The DAC37J82 and DAC38J82 provide the bandwidth, performance, small footprint and low power consumption needed for multi-mode 2G/3G/4G cellular base stations to migrate to more advanced technologies, such as LTE-Advanced and carrier aggregation on multiple antennas.

8.2 Typical Applications

8.2.1 Low-IF Wideband LTE Transmitter

Figure 209 shows an example block diagram for a direct conversion radio. Here it has been assumed that the desired output bandwidth is 80-MHz which could be, for instance, four 20-MHz LTE signals. It is also assumed that digital pre-distortion (DPD) is used to correct 3rd order distortion so the total DAC output bandwidth is 240 MHz. Interpolation is used to output the signal at the highest sampling rate possible to simplify the analog filtering requirements and move high order harmonics out of band. The internal PLL is used to generate the final DAC output clock from a reference clock of 307.2 MHz. The complex mixer will be used to place the baseband input signal at a desired intermediate frequency (IF). The maximum serdes rate that the chosen FPGA supports is 12.5 Gbps and the minimum number of serdes lanes is desired.

Figure 209. Low-IF Wideband LTE Transmitter Diagram

Typical Applications (continued)

8.2.1.1 Design Requirements

For this design example, use the parameters listed in the table below as the input parameters.

DESIGN PARAMETER	EXAMPLE VALUE
Signal Bandwidth (BW _{signal})	80 MHz
Total DAC Output Bandwidth (BW _{total})	240 MHz
DAC PLL	On
DAC PLL Reference Frequency	307.2 MHz
Maximum FPGA Serdes Data Rate	12.5 Gbps

8.2.1.2 Detailed Design Procedure

8.2.1.2.1 Data Input Rate

Nyquist theory says that the data rate must be at least two times the highest signal frequency. The data will be sent to the DAC as complex baseband data. For 240 MHz of signal bandwidth only 120 MHz of input bandwidth is needed, setting the minimum data input rate as 240 MSPS. Further, the process of interpolation requires low pass filters that limit the useable input bandwidth to about 40 percent of F_{data}. Therefore, the minimum data input rate is 300 MSPS. The standard telecom data rate of 307.2 MSPS is chosen.

8.2.1.2.2 Intermediate Frequency

The intermediate frequency is chosen to keep low order harmonics out of band while staying low enough to not degrade the ACPR performance. The band of interest is 240 MHz wide, while the signal bandwidth is 80 MHz wide. The lowest frequency that the second harmonic of the signal will fall at is given on the left side of the inequality shown below based on the chosen IF center frequency. The highest frequency in the band of interest (Total DAC Output Bandwidth) is the right side of the inequality. Solving the inequality for IF and choosing a center frequency higher than that will keep the second harmonic out of the bandwidth of interest.

$$(IF - BW_{\text{signal}} / 2) * 2 \geq IF + BW_{\text{total}} / 2 \quad (3)$$

The lowest IF that satisfies the inequality is shown below.

$$IF \geq BW_{\text{signal}} + BW_{\text{total}} / 2 \quad (4)$$

So for a signal bandwidth of 80 MHz and a total bandwidth of 240 MHz, the lowest IF that satisfies the inequality is 200 MHz. Choose 220 MHz to move HD2 slightly away from the band. The full complex mixer can be enabled with the NCO frequency chosen as 220 MHz to realize this IF frequency.

8.2.1.2.3 Interpolation

It is desired to use the highest DAC output rate as possible to move the DAC images further from the signal of interest to ease the analog filter requirements. The DAC output rate must be greater than two times the highest output frequency, in this case $2 * (220 \text{ MHz} + BW_{\text{total}} / 2) = 680 \text{ MHz}$. The table below shows the possible DAC output rates based on the data input rate and available interpolation settings. The DAC image frequency is also listed. Based on the result, 8x interpolation will push the image frequency 1777.6 MHz away from the band of interest, so the DAC output rate is chosen as 2457.6 MSPS.

Although not shown the high output rate also pushes higher order harmonics out of the band of interest that would have aliased back in at 1228.8 MSPS.

INTERPOLATION	DAC OUTPUT RATE	POSSIBLE?	LOWEST IMAGE FREQUENCY	DISTANCE FROM BAND OF INTEREST
1	307.2 MSPS	No	N/A	N/A
2	614.4 MSPS	No	N/A	N/A
4	1228.8 MSPS	Yes	888.8 MHz	548.8 MHz
8	2457.6 MSPS	Yes	2117.6 MHz	1777.6 MHz
16	4915.2 MSPS	No	N/A	N/A

8.2.1.2.4 DAC PLL Setup

The reference frequency from an onboard clock chip, like the LMK04828, is 307.2 MHz. It is desired to use the highest PFD update rate to maintain the best phase noise performance, but not too high to avoid spurs, therefore the N Divider is chosen to be 2 for a PFD frequency of 153.6 MHz. In order to have the feedback side of the PFD be equal to the reference side (153.6 MHz) and create a DACCLK rate of 2457.6 MHz, the M Divider must be set to 16. Using Table 29, it is found that a VCO frequency of 4915.2 MHz can be used to generate a DACCLK frequency of 2457.6 MHz, so the Prescaler is set to 2 and the H-band VCO is selected.

8.2.1.2.5 Serdes Lanes

It is desired to use the minimum number of serdes lanes while staying under the maximum serdes line rate possible with the chosen FPGA. In the design requirements, the FPGA maximum serdes data rate was given as 12.5 Gbps. For the chosen input data rate of 307.2 MSPS and with 8b/10b encoding on the serdes lanes, each DAC requires a serialized data rate of 6144 Mbps, as given by the equation below.

$$\text{Serialized Data Rate} = F_{\text{data}} * 16 * (10 / 8) \quad (5)$$

The total serialized data rate with a dual DAC is 6144 Mbps * 2 = 12.288 Gbps. This total serialized data rate is split among the total number of lanes. The table below shows the line rate versus the total number of lanes. One lanes running at 12.288 Gbps is chosen since the minimum number of lanes is desired. This sets the JESD204B mode (LMF) for the DAC as 124 mode.

NUMBER OF LANES	LINE RATE	POSSIBLE?
1	12.288 Gbps	Yes
2	6.144 Gbps	Yes
4	3.072 Gbps	Yes
8	1.536 Gbps	Yes

8.2.1.3 Application Performance Plots

8.2.2 Zero-IF Wideband Transmitter

The block diagram shown in [Figure 212](#) also applies for a zero-IF wideband transmitter. However in this case the signal bandwidth is 192 MHz and digital predistortion is used to correct third and fifth order distortion, meaning the total bandwidth of interest is 960 MHz. Interpolation is used to output the signal at the highest sampling rate possible to simplify the analog filtering requirements. The DAC sample clock is provided directly from a clock chip, such as TI's LMK04828. The maximum serdes rate that the chosen FPGA supports is 12.5 Gbps and the minimum number of serdes lanes is desired.

Figure 212. Zero-IF Wideband Transmitter Diagram

8.2.2.1 Design Requirements

For this design example, use the parameters listed in the table below as the input parameters.

DESIGN PARAMETER	EXAMPLE VALUE
Signal Bandwidth (BW_{signal})	192 MHz
Total DAC Output Bandwidth (BW_{total})	960 MHz
DAC PLL	Off
Maximum FPGA Serdes Data Rate	12.5 Gbps

8.2.2.2 Detailed Design Procedure

8.2.2.2.1 Data Input Rate

In this application the total complex bandwidth is 960 MHz meaning that at least 480 MHz of real bandwidth is needed, setting the minimum data input rate at 960 MSPS. However, the process of interpolation requires digital low pass filters that limit the useable input bandwidth to about 40 percent of F_{data} . Therefore, the minimum data input rate is 1.2 GSPS.

8.2.2.2.2 Interpolation

It is desired to use the highest DAC output rate as possible to move the DAC images further from the signal of interest to ease the analog filter requirements. The DAC output rate must be greater than two times the highest output frequency, in this case $2 * 960 \text{ MHz} / 2 = 960 \text{ MHz}$. The table below shows the possible DAC output rates based on the data input rate and available interpolation settings. The DAC image frequency is also listed. Based on the result, 2x interpolation is chosen which will push the image frequency 1.44 GHz away from the band of interest.

INTERPOLATION	DAC OUTPUT RATE	POSSIBLE?	LOWEST IMAGE FREQUENCY	DISTANCE FROM BAND OF INTEREST
1	1.2 GSPS	Yes	720 MHz	240 MHz
2	2.4 GSPS	Yes	1920 MHz	1440 MHz
4	4.8 GSPS	No	N/A	N/A
8	9.6 GSPS	No	N/A	N/A
16	19.2 GSPS	No	N/A	N/A

8.2.2.2.3 Serdes Lanes

It is desired to use the minimum number of serdes lanes while staying under the maximum serdes line rate possible with the chosen FPGA. In the design requirements, the FPGA maximum serdes data rate was given as 12.5 Gbps. For the chosen input data rate of 1.2 GSPS and with 8b/10b encoding on the serdes lanes, each DAC requires a serialized data rate of 24 Gbps, as given by the equation below.

$$\text{Serialized Data Rate} = F_{\text{data}} * 16 * (10 / 8) \quad (6)$$

The total serialized data rate with a quad DAC is 24 Gbps * 2 = 48 Gbps. This total serialized data rate is split among the total number of lanes. The table below shows the line rate versus the total number of lanes. Four lanes must be chosen to support this data rate. This sets the JESD204B mode (LMF) for the DAC as 421 mode.

NUMBER OF LANES	LINE RATE	POSSIBLE?
1	48 Gbps	No
2	24 Gbps	No
4	12 Gbps	Yes
8	6 Gbps	Yes

8.2.2.2.4 LO Feedthrough and Sideband Correction

Although the I/Q modulation process will inherently reduce the level of the RF sideband signal, a zero-IF system will likely need additional sideband suppression to maximize performance. Further, any mixing process will result in some feedthrough of the LO source. The DAC39J82 contains digital features to cancel both the LO feedthrough and sideband signal. The LO feedthrough is corrected by adding a DC offset to the DAC outputs until the LO feedthrough is suppressed. The sideband suppression can be improved by correcting gain, phase, and group delay differences between the I and Q analog outputs. The phase and gain adjustments are made using the QMC block of the DAC while the group delay adjustments are done using the small fractional delay filter. First the phase should be adjusted to suppress the sideband signal at low DAC output frequencies due to phase error. Then the gain can be adjusted to further improve the suppression. Finally, the small fractional filter can be used to improve the sideband suppression across the rest of the signal bandwidth.

8.2.2.3 Application Performance Plots

Figure 213. 192MHz Wideband 256QAM Signal Spectrum

Figure 214. 192MHz Wideband 256QAM Signal ACPR

8.3 Initialization Set Up

The following start up sequence is recommended to power up the DAC39J82.

1. Set TXENABLE low.
2. Supply all 0.9-V supplies (VDDDIG09, VDDT09, VDDDAC09, VDDCLK09), all 1.8-V supplies (VDDR18, VDDS18, VQPS18, VDDIO18, VDDAPLL18, VDDAREF18), and all 3.3-V supplies (VDDADAC33). The supplies can be powered up simultaneously or in any order. There are no specific requirements on the ramp rate for the supplies.
3. RESET the JTAG port by either toggling TRSTB low if using the JTAG port or holding TRSTB low if not using JTAG.
4. Start the DACCLK generation.
5. Toggle RESETB low to reset the SIF registers.
6. Program the DAC PLL settings (*config26*, *config49*, *config50*, *config51*). If the PLL is not used, set *pll_sleep* and *pll_reset* to "1" and *pll_ena* to "0".
7. Program the SERDES settings (*config61*, *config62*) including the *serdes_clk_sel* and *serdes_refclk_div*.
8. Program the SERDES lane settings (*config63*, *config71*, *config73*, *config74*, *config96*).
9. Program *clkjesd_div*, *cdrvser_sysref_mode*, and *interp*.
10. Program the JESD settings (*config3*, *config74-77*, *config79*, *config80-85*, *config92*, *config97*).
11. Program the DIG block settings (NCO, PA protection, QMC, fractional delay, etc.) and set the preferred SYNC modes for the digital blocks (*config30-32*).
12. Verify the SERDES PLL lock status by checking the SERDES PLL alarms: *alarm_rw0_pll* (alarm for lanes 0 through 3) and *alarm_rw1_pll* (alarm for lanes 4 through 7).
13. Set *init_state* to "0000" and *jesd_reset_n* to "1" to start the JESD204B link initialization.
14. Start the SYSREF generation.
15. Enable transmission of data by asserting the TXENABLE pin or setting *sif_txenable* to "1".
16. Clear the alarms, then wait approximately 1-2μs and check values.
17. Verify that DAC output is the desired output.

9 Power Supply Recommendations

The DAC39J82 uses three different power supply voltages. Some of the DAC power supplies are noise sensitive. The table below is a summary of the various power supply of the DAC. Care should be taken to keep clean power supplies routing away from noisy digital supplies. It is recommended to use at least two power layers. Avoid placing digital supplies and clean supplies on adjacent board layers and use a ground layer between noisy and clean supplies if possible. All supplies pins should be decoupled as close to the pins as possible using small value capacitors, with larger bulk capacitors placed further away.

POWER SUPPLY	VOLTAGE	NOISE SENSITIVE?	RECOMMENDATION
VDDADAC33	3.3 V	Yes	Provide clean voltage, avoid spurious noise
VDDAPLL18	1.8 V	Yes	Provide clean voltage, avoid spurious noise
VDDAREF18	1.8 V	Yes	Provide clean voltage, avoid spurious noise
VDDCLK09	0.9 V	Yes	Provide clean voltage, avoid spurious noise
VDDDAC09	0.9 V	Yes	Provide clean voltage, avoid spurious noise
VDDDIG09	0.9 V	No	Digital supply, keep separated from noise sensitive 0.9 V supplies.
VDDIO18	1.8 V	No	No concern
VDDR18	1.8 V	Yes	Provide clean voltage
VDDS18	1.8 V	No	No concern
VDDT09	0.9 V	Yes	Provide clean voltage
VQPS18	1.8 V	No	No concern

10 Layout

10.1 Layout Guidelines

- DAC output termination resistors should be placed as close to the output pins as possible to provide a DC path to ground and set the source impedance.
- For PLL mode, if the external loop filter is not used then leave the pin floating without any board routing. Signals coupling to this node may cause clock mixing spurs in the DAC output.
- Route the high speed serdes lanes as impedance-controlled, tightly-coupled, differential traces.
- Maintain a solid ground plane under the serdes lanes without any ground plane splits.
- AC couple the serdes lines between the logic device and the DAC using 0201 size capacitors that maintain low impedance at the serialized data rate.
- Simulation of the serdes channel is recommended to verify JESD204B standard compliance to ensure compatibility between devices.
- Keep the SYSREF routing away from the DACCLK routing to reduce coupling. Using a pulsed SYSREF or disabling a continuous SYSREF is recommended during normal operation to avoid spurs in the output spectrum.
- Keep routing for RBIAS short, for instance a resistor can be placed on the bottom of the board directly connecting the RBIAS ball to a GND ball.
- Decoupling capacitors should be placed as close to the supply pins as possible, for instance a capacitor can be placed on the bottom of the board directly connecting the supply ball to a GND ball.
- Noisy power supplies should be routed away from clean supplies. Use two power plane layers, preferably with a GND layer in between.

11 Device and Documentation Support

11.1 Trademarks

All trademarks are the property of their respective owners.

11.2 Electrostatic Discharge Caution

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

11.3 Glossary

[SLYZ022](#) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical packaging and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
DAC39J82IAAV	ACTIVE	FCBGA	AAV	144	168	Green (RoHS & no Sb/Br)	SNAGCU	Level-3-260C-168 HR	-40 to 85	DAC39J82I	Samples
DAC39J82IAAVR	ACTIVE	FCBGA	AAV	144	1000	Green (RoHS & no Sb/Br)	SNAGCU	Level-3-260C-168 HR	-40 to 85	DAC39J82I	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
